1 DESCRIPTION

1.1 Purpose

This document provides an overview of the data included in this NEON Level 1 data product, the quality controlled product generated from raw Level 0 data, and associated metadata. In the NEON data products framework, the raw data collected in the field, for example, the dry weights of litter functional groups from a single collection event are considered the lowest level (Level 0). Raw data that have been quality checked via the steps detailed herein, as well as simple metrics that emerge from the raw data are considered Level 1 data products. The text herein provides a discussion of measurement theory and implementation, data product provenance, quality assurance and control methods used, and approximations and/or assumptions made during L1 data creation.

1.2 Scope

This document describes the steps needed to generate the L1 data product Plant phenology observations - Repeat phenophase status and intensity measurements collected from individuals along an 800-m transect or from within a fixed plot - and associated metadata from input data. This document also provides details relevant to the publication of the data products via the NEON data portal, with additional detail available in the file, NEON Data Publication Workbook for TOS Plant Phenology Observations (AD[05]), provided in the download package for this data product. This document describes the process for ingesting and performing automated quality assurance and control procedures on the data collected in the field pertaining to TOS Protocol and Procedure: Plant Phenology (AD[07]). The raw data that are processed in this document are detailed in the file, NEON Raw Data Ingest Workbook for TOS Plant Phenology Observations (AD[04]), provided in the download package for this data product. Please note that raw data products (denoted by 'DP0') may not always have the same numbers (e.g., '10033') as the corresponding L1 data product.

3 DATA PRODUCT DESCRIPTION

The plant phenology observations product provides in-situ observations of the phenological status and intensity of tagged plants (or patches) during discrete observation events. NEON employs status-based monitoring, in which the phenological condition of an individual is reported any time that individual is observed. At every observation bout, records are generated for every phenophase that is occurring and for every phenophase not occurring. With this approach, events (such as leaf emergence in Mediterranean climates, or flowering in many desert species) that may occur multiple times during a single year, can be captured. Continuous reporting of phenophase status enables quantification of the duration of phenophases rather than just their date of onset while allowing enabling the explicit quantification of uncertainties in phenophase transition dates that are introduced by monitoring in discrete temporal bouts.

Observation bouts are completed by NEON field technicians and occur at core and relocatable terrestrial sites according to site- and season-specific sampling intervals. Species and sampling schedules for plant phenological observations vary between sites. For an overview of the data collection strategy, see the NEON TOS Science Design - Plant Phenology AD[06], Elmendorf 2016, as well as the plant phenology protocol AD[07]).

Products derived from this sampling include the observed phenophase status (whether or not a phenophase is occurring) and the intensity of phenophases for which phenophase status = ‘yes’. According to the USA National Phenology Network (USA-NPN), a phenophase is defined as ‘an observable stage or phase in the annual life cycle of a plant or animal that can be defined by a start and end point’. Phenophase intensity, then, quantifies the degree to which a given phenophase is being expressed (continuous phenomenon, although recorded in bins). The phenophase categories employed by NEON are derived from the USA-NPN (Denny 2014; www.usanpn.org; although not all reproductive phenophases are monitored by NEON technicians due to labor constraints. Taxonomic identification and geolocation data (collected upon tagging of plants, though possibly updated through time), as well as an annual survey of plant size and condition are also provided.

Species for phenology observation are selected based on relative abundance in the Tower airshed. To determine relative abundance, taxonomic and vegetation structure surveys are conducted in all Tower base plots in advance of transect and plot establishment according to the Plant Diversity and Vegetation Structure protocols (AD[09] and AD[08] respectively).

The NEON phenology measurements track sensitive and easily observed indicators of biotic responses to climate variability by monitoring the timing and duration of phenological stages in plant communities. Plant phenology is affected by forces such as temperature, timing and duration of pest infestations and disease outbreaks, water fluxes, nutrient budgets, carbon dynamics, and food availability and has feedbacks to trophic interactions, carbon sequestration, community composition and ecosystem function.

3.1 Spatial Sampling Design

Plant phenology observations occurs at all terrestrial NEON sites along an 800 meter square loop transect (primary) and within a 200 m x 200 m plot located within view of a canopy level, tower-mounted, phenology camera (phenocam). Both the phenocam plot plot and the primary transect are oriented in the four cardinal directions and are situated within the tower airshed where possible (Figure 1). The primary transect is intentionally positioned alongside Tower base plots to facilitate selection of individuals in both the plant phenology and vegetation
structure protocols (Figure 1). Selected individuals along the primary transect are located 1-10 m from the transect in order to minimize trampling and to allow observations without requiring field personnel to leave the transect. To the extent possible, given the heterogeneity in the plant community around the transect, selected individual are distributed evenly around the transect. At sites where the loop transect is located directly north of the NEON Tower, no additional phenocam plot is established. See TOS Science Design for Plant Phenology (AD[06]), TOS Protocol and Procedure: Plant Phenology (AD[07]), TOS Science Design for Spatial Sampling (AD[02]) and TOS Science Design for Plant Diversity (AD[09]) for further details.

![Figure 1: Placement of phenology transect relative to the NEON tower, airshed and tower plots](image)

3.2 Temporal Sampling Design

All individuals/patches selected for phenology monitoring within a site are monitored with the same frequency; the primary transect and the phenocam plot are monitored on the same schedule. Sampling schedules are either 1) year round, 2) seasonal, or 3) hybrid.

*Year round sampling schedule.* At sites with limited or no pronounced dormant season (e.g., tropical, southeast), or >1 growing season/year (e.g., desert southwest), observation bouts will occur throughout the entire year at a frequency of 1x/week.

*Seasonal sampling schedule.* At sites with well-defined, discrete, growing seasons, the seasonal sampling fre-
Frequency varies to capture rapid changes during phenological transition periods. The sampling season begins with at least one observation each year within 7 days prior to the onset of springtime activity (variably defined as breaking leaf buds, breaking needle buds, emerging needles, or initial growth; see column 2 in Table 1). Intensive sampling (2-3x/week) occurs in conjunction with the onset of springtime phenological activity and continues through the early spring development. Once >50% of leaf/canopy development has occurred sampling can be reduced to once a week until full canopy has developed. Post 95% canopy development, sampling is further reduced to once every other week until reproductive phenophases are complete. A second intensive stage (sampling twice a week) begins again in the fall to capture leaf senescence/coloring, then reduces to once a week through the end of the season.

*Hybrid sampling schedule.* In some sites, especially those in arid or semiarid environments, phenology may be driven by moisture rather than temperature. In this case, sampling dates and frequency may be more episodic but sampling has the same goal of maintaining high frequency during periods of rapid change, but are flexible to start and end sampling multiple times throughout the year. One example of a hybrid sampling scheduled is starting with year round regular sampling (1x/week), increasing frequency during periods of growth, then dropping to <1/week during dormant periods. The varied intensity is intended to strategically use sampling periods in order to monitor phases of rapid phenological change, while minimizing labor/disturbance associated with frequent measurements during times of year of less rapid change or inactivity (Table 1).

Phenological observations are recorded on all individuals each time monitoring is performed, unless the end-of-season phenophase/trigger has been reached for a particular individual, in which case, monitoring of that individual is not required for the remainder of the season. See TOS Protocol and Procedure: Plant Phenology (AD[07]) for additional details on phenophase events that trigger changes to observation frequency.

### 3.3 Variables Reported

All variables reported from the field or laboratory technician (L0 data) are listed in the file, NEON Raw Data Ingest Workbook for TOS Plant Phenology Observations (AD[04]). All variables reported in the published data (L1 data) are also provided separately in the file, NEON Data Publication Workbook for TOS Plant Phenology Observations (AD[05]).

Field names have been standardized with Darwin Core terms ([http://rs.tdwg.org/dwc/](http://rs.tdwg.org/dwc/); accessed 16 February 2014), the Global Biodiversity Information Facility vocabularies ([http://rs.gbif.org/vocabulary/gbif/](http://rs.gbif.org/vocabulary/gbif/); accessed 16 February 2014), the VegCore data dictionary ([https://projects.nceas.ucsb.edu/nceas/projects/bien/wiki/VegCore](https://projects.nceas.ucsb.edu/nceas/projects/bien/wiki/VegCore); accessed 16 February 2014), where applicable. NEON TOS spatial data employs the World Geodetic System 1984 (WGS84) for its fundamental reference datum and GEOID09 for its reference gravitational ellipsoid. Latitudes and longitudes are denoted in decimal notation to six decimal places, with longitudes indicated as negative west of the Greenwich meridian.

Some variables described in this document may be for NEON internal use only and will not appear in downloaded data.
### 3.4 Spatial Resolution and Extent

The finest spatial resolution at which phenology data will be tracked is per individual (n <= 100 individuals per primary phenology plotID).

- **individuallID** (unique ID given to the tagged individual or patch) → **plotID** (unique ID given to transect or plot) → **siteID** (ID of NEON site) → **domainID** (ID of a NEON domain).

The basic spatial data included in the data downloaded include the latitude, longitude, and elevation of the centroid of the plot where sampling occurred + associated uncertainty due to GPS error. Shapefiles of all NEON Terrestrial Observation System sampling locations can be found in the Document Library: [http://data.neonscience.org/documents](http://data.neonscience.org/documents).

To derive a more precise estimate of the location of each individual, there are two options:

- Use the def.calc.geo.os function from the geoNEON package, available here: [https://github.com/NEONScience/NEON-geolocation](https://github.com/NEONScience/NEON-geolocation)
- Or follow these steps to perform the same calculation:

  1. The namedLocation field in the data is the named location of the transect or plot; more precise geographic data require the named location of the nearest pointID. Construct the named location of the pointID associated with each record in phe_perindividual by first looking up the pointID of the two pointID on either side of the transectMeter labeled referencePoint_A and referencePoint_B respectively (Table 1) then concatenating the fields for namedLocation and referencePoint as: namedLocation + ‘.’ + referencePoint, e.g. referencePoint ‘W’ of namedLocation ‘HARV_053.phenology.phe’ has a complete named location of ‘HARV_053.phenology.phe.W’.

</tbody>
</table>

2. Use the API ([http://data.neonscience.org/api](http://data.neonscience.org/api); e.g. [http://data.neonscience.org/api/v0/locations/HARV_053.phenology.phe.W](http://data.neonscience.org/api/v0/locations/HARV_053.phenology.phe.W)) to query for elevation("locationElevation"), easting("locationUtmEasting"), northing("locationUtmNorthing"), coordinateUncertainty ("Value for Coordinate uncertainty"), elevationUncertainty ("Value for Elevation uncertainty"), and utmZone ("locationUtmZone") as inputs to the next step.
3. Assign the offsetDirection based on the value in phe_perindividual_pub.transectMeter and phe_perindividual_pub.directionFromTransect according to guidelines in Table 2.

4. Determine the geolocation of the transectMeter for each individual in utms as the weighted mean of the northing (in utms) of reference_pointA and reference_pointB, and the weighted mean of the easting referencePoint_A and referencePoint_B, where the weighted mean is defined as:

$$\bar{x} = \sum_{i=1}^{n} w_i x_i$$  \hspace{1cm} (1)

where $x_i$ is the northing or easting of the reference points, and

$$w_b = \frac{\text{transectMeter}_i - \text{transectMeter}_{\text{refPtA}}}{100}$$  \hspace{1cm} (2)

where $\text{transectMeter}_{\text{refPtA}}$ is the value from Table 1 and

$$w_a = 1 - w_b$$  \hspace{1cm} (3)

5. Calculate the geolocation of the actual plant by adding or subtracting the ninetyDegreeDistance from the geolocation of the transectMeter, according to the offsetDirection specified in Table 2.

**Example:** transectMeter=85, ninetyDegreeDistance=4, directionFromTransect=right. An observer is assumed to be 85% of the way between the SW and W reference points of the plot. If the SW reference point is at (0,0) (easting and northing, in utms), and the W reference point is at (-5, 103), for example, the true position of the transectMeter is at easting = (0.15 × 0 + 0.85 × -5) = -4.25 and northing = (0.15 × 0 + 0.85 × 103) = 87.55. Since the observer is between 0-200m on the transect, s/he is traveling north, so a ninetyDegreeDistance of 4 to the right is equivalent to an offset of 4m E. The position of the plant in utms is (87.55, -0.25).
6. Increase coordinateUncertainty by an appropriate amount (suggested 5 m) to account for error introduced by navigating around the transect. Error may also be introduced due to tape stretching on initial establishment and deviations from the the transect in order to avoid obstacles.

3.5 Temporal Resolution and Extent

The finest resolution at which temporal data are reported is the date or dayOfYear, the status of each phenophase, for a tagged individual, on the day of observation.

The NEON Data Portal currently provides data in monthly files for query and download efficiency. Queries including any part of a month will return data from the entire month. Combined, data from each observation date contribute to a time course that may be used to assess phenophase transition dates, duration and change across years. Code to stack files across months is available here: https://github.com/NEONScience/NEON-utilities

3.6 Associated Data Streams

individualID is a linking variable that ties phenophase observations and associated metadata to the Woody plant vegetation structure (NEON.DP1.10098), the Non-herbaceous perennial vegetation structure (NEON.DP1.10045), the Plant foliar physical and chemical properties (NEON.DP1.10026), and Plant canopy leaf mass per area (NEON.DP1.10048) data products. Users are advised to leverage data from all associated data products to provide context to phenology data.

3.7 Product Instances

There are approximately 50 plant phenology observation bouts per calendar year at every terrestrial site. There are no more that 100 sampling points (individuals or patches) located along the phenology transect and no more than 9 sampling points within the phenocam plot. The number of phenophases observed varies by growth form and ranges from 1 phenophase (cactus) to 7 phenophases (semi-evergreen broadleaf). In addition to the 50 phenophase observation bouts, is a bout to collect annual size and disease status measurements from each sampling point. Thus, no single site should ever exceed 38,259 data product instances in a given calendar year.

3.8 Data Relationships

The protocol dictates that each sampling location (individual or patch) is established once. Each location is tagged and assigned an identifier that is unique across the Observatory; phe_perindividual.individuialID. Observations of phenophase status in phe_statusintensity and annual measurements of size and health conditions in phe_perindividualperyear are linked to location metadata contained in phe_perindividual via individualID. Duplicates and/or missing data may exist where protocol and/or data entry aberrations have occurred; users should check data carefully for anomalies before joining tables.

phe_perindividual - > One record expected per individualID for all time. Duplicate records may exist if location or taxon information is updated. If duplicate records are present in this table, users are advised to retain the record with the latest editedDate.
phe_perindividualperyear -> One record expected per individualID per year. Duplicate records for a given individualID may exist if measurements are collected on different days in which case users are advised to merge non-null values for a given individualID. If full duplicate records are present in this table, or duplicates for which there are conflicting values for a given field, users are advised to retain the record with the latest editedDate.

phe_statusintensity -> One record expected per individualID x phenophaseName combination for a given date. Duplicate records may exist if edits are made to a record (e.g. phenophaseStatus = ‘uncertain’, edited to either a ‘yes’ or ‘no’ based on review with lead technician). If duplicate records are present in this table, users are advised to retain the record with the latest editedDate.

4 DATA QUALITY

4.1 Data Entry Constraint and Validation

Many quality control measures are implemented at the point of data entry within a mobile data entry application or web user interface (UI). For example, data formats are constrained and data values controlled through the provision of dropdown options, which reduces the number of processing steps necessary to prepare the raw data for publication. An additional set of constraints are implemented during the process of ingest into the NEON database. The product-specific data constraint and validation requirements built into data entry applications and database ingest are described in the document NEON Raw Data Ingest Workbook for TOS Plant Phenology Observations, provided with every download of this data product. Contained within this file is a field named ‘entryValidationRulesForm’, which describes syntactically the validation rules for each field built into the data entry application. Data entry constraints are described in Nicl syntax in the validation file provided with every data download, and the Nicl language is described in NEON’s Ingest Conversion Language (NICL) specifications (AD[15]).

4.2 Automated Data Processing Steps

Following data entry into a mobile application or web user interface, the steps used to process the data through to publication on the NEON Data Portal are detailed in the NEON Algorithm Theoretical Basis Document: OS Generic Transitions (AD[14]).

4.3 Data Revision

All data are provisional until a numbered version is released; the first release of a static version of NEON data, annotated with a globally unique identifier, is planned to take place in 2020. During the provisional period, QA/QC is an active process, as opposed to a discrete activity performed once, and records are updated on a rolling basis as a result of scheduled tests or feedback from data users. The Change Log section of the data product readme, provided with every data download, contains a history of major known errors and revisions.
4.4 Quality Flagging

The dataQF field in each record is a quality flag for known issues applying to the record, added by NEON Science upon data review.

5 DATA PROCESSING STEPS

Following data entry into a mobile application of web user interface, the steps used to process the data through to publication on the NEON Data Portal are detailed in the NEON Algorithm Theoretical Basis Document: OS Generic Transitions (AD[12]).
