Figure 3. Example of injection calculation worksheet for NaCl. Modified from LINX II. The squares in yellow are the ones that you are free to adjust based on your stream conditions. Start by entering your estimated stream Q. In this example the, we are targeting to increase the stream conductivity by 7 mg/L (~ 14 µS/cm). Our stream flow is 60 L/s and we want to release for an hour and mix our salt into 17 L of water. If we have a release rate of 200 mL/min, the spreadsheet calculates that we can actually pump for 1.4 hours before we are out of solution. In order to make up this salt solution, we need to weight out 3531 g of NaCl. 32

| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

1 OVERVIEW

1.1 Background

Stream metabolism measurements quantify the amount of primary production and respiration occurring within a reach (both benthic and water-column) by measuring changes in oxygen (O₂) concentration within a stream segment. Changes in oxygen concentration can occur from both biological, such as primary production (O₂ gain in the water column) and respiration (O₂ loss), and physical, such as gas exchange with the atmosphere (i.e., reaeration, the gain of O₂ into the water, or deaeration, the loss of O₂ from the water) as oxygen diffuses across the water-air interface. In order to understand the biological controls on oxygen within our systems, we must first account for the physical controls (e.g., reaeration or gas exchange).

Reaeration (i.e., gas exchange) is the movement of oxygen from the atmosphere into the water, and is measured as the net rate (i.e. gain and loss of oxygen) at which gas exchanges across the air-water interface. Stream reaeration rates are influenced by several physical characteristics of the site, such as the temperature, turbulence, wind, tributary and groundwater inputs, and oxygen concentration gradient across the interface. The reaeration rate coefficient (K_2) represents the combined effects of these physical characteristics. In turbulent and low productivity streams, reaeration rate coefficients may be the dominant term in the oxygen balance and for determining the potential for an oxygen deficit. Thus, it is imperative to quantify stream reaeration rates accurately as a small error in reaeration rates can dramatically skew stream metabolism results.

1.2 Scope

This document provides a change-controlled version of Observatory protocols and procedures. Documentation of content changes (i.e. changes in particular tasks or safety practices) will occur via this change-controlled document, not through field manuals or training materials.

1.2.1 NEON Science Requirements and Data Products

This protocol fulfills Observatory science requirements that reside in NEON’s Dynamic Object-Oriented Requirements System (DOORS). Copies of approved science requirements have been exported from DOORS and are available in NEON’s document repository, or upon request.

Execution of this protocol procures samples and/or generates raw data satisfying NEON Observatory scientific requirements. These data and samples are used to create NEON data products, and are documented in the NEON Scientific Data Products Catalog (RD[03]).

1.3 Acknowledgments

The field protocol used by NEON for measuring stream reaeration in small, wadeable streams follows the general requirements set forth by Lotic Intersite Nitrogen eXperiment (LINX) II (2004), the laboratories of Dr. Bob Hall, University of Wyoming, and Dr. Michelle Baker, Utah State University, as well as outlined in Hall and Tank (2003).

2.4 Definitions

Conservative tracer: A nonreactive chemical tracer that remains constant as it follows the flow of water.
Ex. Chloride (Cl⁻) or Bromide (Br⁻)

Deaeration: Loss of oxygen molecules from a liquid (or gas).

Diffusion: The movement of particles from an area of higher concentration to an area of lower concentration.

Discharge: The volume of water flowing past a point on a stream during a specified unit of time.

Ecosystem Metabolism: In streams, ecosystem metabolism is the measure of the production and respiration of organic matter. It is often used as a measure of stream function because it is a measure of the interaction between organic matter and nutrients across a stream reach.

Gas Exchange Rate: See reaeration rate.

Inert gas: A gas that does not interact with the environment thus making it a useful tracer of gas exchange across the air-water interface.

Logger: Device used for making systematic recordings of measurements or observations.

NaCl: Sodium Chloride (salt). The Cl of the NaCl compound is the conservative tracer used in this protocol.

Plateau: Time at which the stream is at steady state with the conservative tracers (i.e. stream concentration remains constant)

Reaeration: Physical movement of gas from the atmosphere to a body of water.

Reaeration rate (AKA gas exchange rate): The net rate at which gas exchanges across the air-water interface (i.e. gain and loss of oxygen).

SF₆: Sulfur Hexafluoride. The inert (non-reactive) gas in this protocol.

| | | |
|---|---------------------------|-------------------------|

| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

Travel time: The length of time it would take an average grouping of water molecules to travel from one location within a watershed to another location.

3 METHOD

This protocol outlines the procedures required to measure gas exchange (i.e., reaeration rate coefficient, K_2) from the atmosphere to the water by use of an inert (i.e., will not interact with any biogeochemical processes) gas tracer (e.g., Sulfur Hexafluoride (SF_6)), as well as a conservative tracer (e.g., NaCl) to account for groundwater inputs to the system. Stream reaeration is often measured by injecting an inert gas (e.g., Propane or SF_6) into the stream water at the top of a study reach. Because the inert gas concentration is higher in the stream than the atmosphere, the gas diffuses out of the stream (Figure 18). The diffusion rate of the inert gas is proportional to the O_2 gas exchange rate (Wanninkhof 1992, Raymond et al. 2012). Thus, measurements of the concentration of the inert gas are used to calculate an O_2 reaeration (or deaeration) rate coefficient (K_2). To account for dilution due to surface or groundwater inputs, a conservative solute tracer such as chloride (Cl^-) or bromide (Br^-) is added to the stream in addition to the inert gas.

This protocol will only be implemented in small, wadeable streams. Reaeration measurements should be conducted when no other work is being conducted in the stream, as disturbance of sediments and habitat may influence reaeration results.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

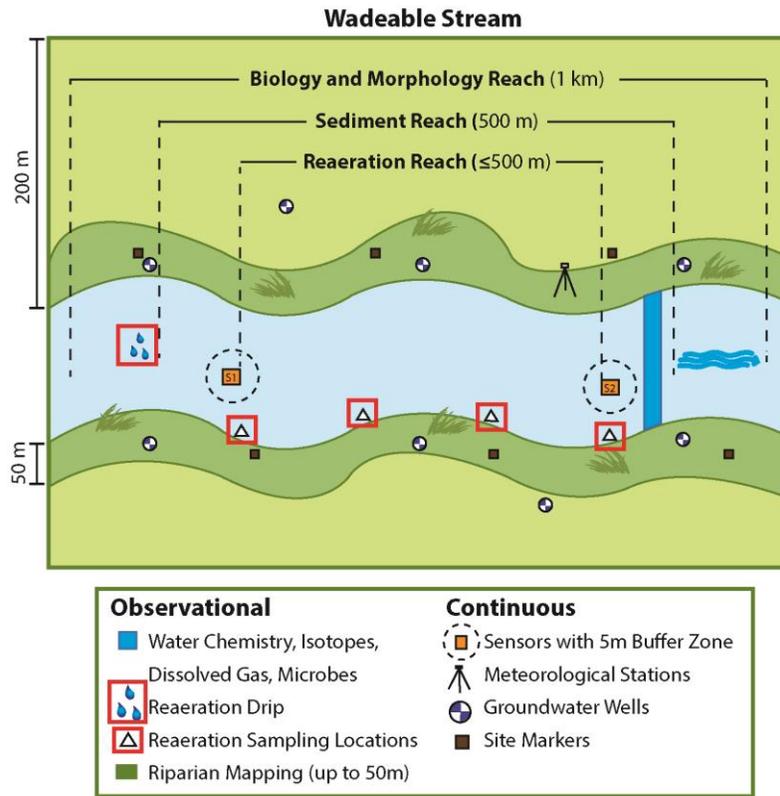

Figure 1. A generic wadeable stream site layout example with reaeration sampling stations

Standard Operating Procedures (SOPs), in Section 7 of this document, provide detailed step-by-step directions, contingency plans, sampling tips, and best practices for implementing this sampling procedure. To properly collect and process samples, field technicians **must** follow the protocol and associated SOPs. Use NEON’s problem reporting system to resolve any field issues associated with implementing this protocol.

The value of NEON data hinges on consistent implementation of this protocol across all NEON domains, for the life of the project. It is therefore essential that field personnel carry out this protocol as outlined in this document. In the event that local conditions create uncertainty about carrying out these steps, it is critical that technicians document the problem and enter it in NEON’s problem tracking system.

Quality assurance will be performed on data collected via these procedures according to the NEON Science Performance QA/QC Plan (AD[05]).

3.1 Assumptions

1. Since we are unable to account for losses from our stream to groundwater, a critical assumption of reaeration measurements is that groundwater losses are minimal.

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

2. Assume tracers (both the inert gas and conservative tracer) are uniformly mixed in the channel cross section.

4 SAMPLING SCHEDULE

4.1 Sampling Frequency and Timing

Reaeration measurements shall be completed up to 10 times annually during NEON Site Characterization activities and up to 6 times annually during NEON Operations in wadeable stream locations. Sites that are high risk sites for flooding resulting in changes in stream morphology may be requested to continue to collect reaeration 10 times per year. Sampling events should be spread out throughout the year so as to collect a range of flows.

Timing of sampling is site specific and determined by rules developed using historical flow regime and environmental data. For example, streams with little or no flow during the summer dry-season are sampled more intensively during wet periods. Streams with snowmelt-dominated hydrographs are sampled more intensively during spring/summer-elevated flows than during winter snow-covered months.

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

4.2 Criteria for Determining Onset and Cessation of Sampling

Reaeration, discharge, and other physical parameters are used to develop a reaeration-discharge curve. Once the curve is established, simultaneous measurements of reaeration and discharge must be made over a range of discharges to ensure the curve has not shifted over time. Therefore, the production of a continuous record of reaeration requires periodic manual reaeration measurement checks during Operations. In the event that the curve check does not produce results similar to the original reaeration-rating curve, such as after a major flooding or scouring event, a new curve will need to be established.

In general, the reaeration curve will be checked for a high, low and average discharge event. Rating curve checks may also be completed during times selected to help fill in gaps in the measured data for the reaeration-discharge rating curve (i.e., when discharge is in a range with minimal or no reaeration measurements) in order to refine parts of the curve with little data. Stream discharge shall be measured on all reaeration measurement days RD[07].

4.3 Timing for Laboratory Processing and Analysis

Reaeration samples collected at a given site shall be processed within 3 hours of the end of sample collection at that site.

4.4 Sampling Timing Contingencies

When unexpected field conditions require deviations from this protocol, the following field implementation guidance must be followed to ensure quality standards are met:

Samples should be processed (shaken, filtered, and transferred to appropriate containers) as soon as possible. If necessary, stream water may be collected in syringes, kept at 4°C, and processed within 3 hours at a base camp or Domain Lab (i.e., if weather dictates the need to leave the field immediately and stream discharge is increasing). Sample collection time, processing station and processing time must be recorded on the Reaeration mobile application.

If weather changes during the reaeration injection making conditions unsafe or if stream discharge increases such that the physical condition of the stream has changed, stop the injection and re-schedule the bout or complete on the next scheduled date in order to have the correct number of bouts per year that were originally scheduled, 6 or 10 bouts.

Monitor the injection equipment during the injection to ensure proper functioning of the salt and gas injection equipment. If equipment malfunctions and can be fixed immediately, do so and continue the experiment, making note of the malfunction on the mobile application. Most malfunctions will cause a change in the rate of gas or salt addition during the injection. Since we are attempting to get the stream to a plateau, changes in rate additions will result in inaccurate data collection (i.e. if the rate changes, it

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

is no longer a constant-rate experiment and data will not accurately represent stream conditions). Thus, the injection will need to be restarted (from the beginning) or rescheduled, following an incident ticket.

Reaeration measurements should not be conducted during or immediately after any fieldwork disrupting the stream bottom (i.e., morphology mapping, invertebrate collection, macrophytes collection, etc.). In streams with a shallow water column, samplers must be cautious not to stir up the benthic sediments when sampling the stream water. Disruption of the sediments by walking or by sampling too close to the stream bottom can contaminate your sample. Thus, always sample upstream from wading activity and minimize suspension of sediments when sampling. If sediments are disrupted, wait until the area has cleared before sampling.

The weather should be checked the day prior to the scheduled field sampling and the schedule adjusted to avoid any major storms. Should it begin raining during the reaeration injection enough to change the flow of the stream, stop the injection and restart at a later date. Reaeration measurements should not be made when the water level and discharge are changing rapidly. If the stream is exhibiting very low flow rates, is disconnected such that it is a series of pools not connected by surface water, or is dry, do not conduct an injection and attempt to re-schedule the bout.

Make a note of any weather or stream conditions that could influence reaeration, including but not limited to wind, channel alterations, activities in the surrounding watershed, prior flood or rain events.

Table 1. Contingent decisions

| Delay/ Situation | Action | Outcome for Data Products |
|---------------------|---|---------------------------|
| Hours | If weather conditions are unsafe for sampling (i.e. lightning, hail or flooding), stop sampling and resume work at a later time or date when conditions are appropriate for protocol implementation | No adverse outcome. |
| | If sampling stirred up sediments or added chemical constituents to the stream/lake (i.e., gas additions) within the past hour, allow the water to clear and disturbance to pass, sample upstream/upwind of the disturbance. | No adverse outcome. |
| Days | If sampling location is dry, frozen, or frozen over, resume work at a later date when stream is flowing. | No adverse outcome. |
| | If stream flow is too low to ensure a travel time of <3 hours, resume work at a later date when conditions are appropriate for protocol implementation. | No adverse outcome. |

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

| | | |
|--|---|---------------------|
| | If sampling location is >20% ice-covered, deploy hobo loggers and complete a salt slug, if safe. This will allow us to still calculate salt-based discharge and travel time. Resume reaeration work at a later date when stream is not ice-covered. | No adverse outcome. |
|--|---|---------------------|

4.5 Criteria for Permanent Reallocation of Sampling Within a Site

Reaeration sampling will occur on the schedule described above at 4 sampling stations within wadeable stream sites (**Figure 1**). Ideally, sampling will occur at these sampling locations for the lifetime of the Observatory (core sites) or the duration of the site’s affiliation with the NEON project (relocatable sites). However, circumstances may arise requiring that sampling within a site be shifted from one particular location to another. The exact distance downstream of the injection location for each station is critical for calculating reaeration rates. Even if a station does not move to a new location, but the stream channel changes length (i.e. increases or decreases in sinuosity), a new distance from the injection location should be recorded. In general, sampling is considered to be compromised when sampling at a location becomes so limited that data quality is significantly reduced. If sampling at a given stream becomes compromised, a problem ticket should be submitted by Field Operations to Science.

There are two main pathways by which sampling can be compromised. Sampling locations can become inappropriately suited to answer meaningful biological questions (e.g., a terrestrial sampling plot becomes permanently flooded or a stream moves after a flood and the location is no longer within the stream channel). Alternatively, sampling locations may be located in areas that are logistically impossible to sample on a schedule that is biologically meaningful.

5 SAFETY

This document identifies procedure-specific safety hazards and associated safety requirements. It does not describe general safety practices or site-specific safety practices.

Personnel working at a NEON site must be compliant with safe field work practices as outlined in the Operations Field Safety and Security Plan (AD[02]) and EHS Safety Policy and Program Manual (AD[01]). Additional safety issues associated with this field procedure are outlined below. The Field Operations Manager and the Lead Field Technician have primary authority to stop work activities based on unsafe field conditions; however, all employees have the responsibility and right to stop their work in unsafe conditions.

Gas cylinders must be secured during transport (i.e., the regulator should not be attached to the tank, the safety cap should be screwed on and the tank should be secured upright during transport so as not to roll around, with the bottom of the tank pointed towards the floor). Never pick up a gas cylinder by the cap. See the Compressed Gas Safety training PowerPoint on the NEON Safety SharePoint Page.

6.2 Training Requirements

All technicians must complete required safety training. Additionally, technicians must complete protocol-specific training for safety and implementation of this protocol as required in Field Operations Job Instruction Training Plan (AD[04]).

See the Compressed Gas Safety training PowerPoint on the NEON Safety SharePoint Page.

6.3 Specialized Skills

Personnel are required to have working knowledge of gas tank handling and usage.

6.4 Estimated Time

The time required to implement a protocol will vary depending on a number of factors, such as skill level, system diversity, environmental conditions, and distance between sample stations. The timeframe provided below is an estimate based on completion of a task by a skilled two-person team (i.e., not the time it takes at the beginning of the field season). Use this estimate as framework for assessing progress. If a task is taking significantly longer than the estimated time, a problem ticket should be submitted.

This protocol requires approximately 1-2 hours of pre-field work activities, such as tracer injection calculations, charging batteries, weighing salt, and labeling bottles. We estimate field sampling and processing requires 2 technicians for 4 hours each sampling day plus travel to and from site. More time (additional 1-2 hours) may be needed in low flows. An additional 1 hour will be required for post-sampling activities in the support facility, such as QC of data entry and sample label checks, sample shipment, and cleaning/maintaining the pump.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

7 STANDARD OPERATING PROCEDURES

SOP A Initial Trip (Note: This step is completed by NEON HQ staff to determine sensor locations.)

A.1 Locate Reaeration Reach (AKA Sensor Reach)

1. Determine Reaeration Reach by determining where in-stream sensors will be placed (completed by HQ), which is representative of the stream and has an injection site (i.e. the station at the top of the reach where we will add the SF₆ gas and NaCl solution) with a good mixing zone and minimizing the inclusion of large pools or dead zones (which increase travel time and water storage).
 - a. There will be 4 sampling stations within the reach, located downstream of the injection site (Figure 7).
 - 1) The 1st sampling station (Station 1 located at Sensor Set 1) should be just downstream of the distance it takes the conservative tracer to completely mix with the stream water (25 - 100 m; higher flow streams often need more length to completely mix). During higher flows, mixing lengths may increase and injection sites may need to be moved upstream.
 - 2) The last sampling station (Station 4) will be located at the bottom of the reaeration reach, located at Sensor Set 2.
2. Locate Reaeration Reach (completed by FOPS). The reaeration is collocated with the sensor reach, where reaeration station 1 is collocated with sensor set 1 and reaeration station 4 is collocated with sensor set 2. The reaeration drip station should be upstream of sensor set 1. Once sensors are installed, be sure to adjust your reaeration stations accordingly to ensure collocation with sensors.

A.2 Determine Reach Length

1. The top of the reach must start with a good mixing zone to completely mix tracer with stream water. Best mixing zones are upstream of shallow pools with converging and diverging flows (Figure 8). This should allow for complete mixing before the first sampling station (Station 1), thus the drip station is often 25 – 100 m upstream of station 1. Wide, slow moving streams may have difficulties mixing. To ensure complete mixing at Station 1, during the continuous NaCl injection measure conductivity across main flowing section of the stream after steady state has been reached (i.e., the conductivity is no longer increasing). Depending on flows this could take 20 minutes to several hours to attain. If the site is well mixed, conductivity should be similar across this main flow.
2. Measure travel time between Station 1 and Station 4 - The best reach lengths are those that take ~40-45 minutes, during baseflow, for water to travel from Station 1 to Station 4. A simple way to estimate water travel time is to place an orange in the stream at Station 1 and follow

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

the orange as it moves downstream for ~40-45 minutes to Station 4. Salt-pulse additions may be necessary to estimate travel time in small streams (<25-30 L/s), where travel time between Stations 1 and 4 is the difference in the timing of the salt profile half-height as it passes station 1 and 4. Adjust Station 4 upstream or downstream to obtain the appropriate travel time.

SOP B Outline of Major Steps on All Reaeration Days

1. Measure Discharge (It is OK to deploy HOBO loggers first).
2. Measure background conductivity and collect a background Cl/Br-sample at each of the four reaeration stations. Deploy loggers at Station 1 and 4 within 0.1 m of the sensor set main support. Suspend the loggers in the water column using the sensor set infrastructure or other temporary feature (i.e. rebar) rather than placing them on the streambed.
3. Continuous injection of inert gas (e.g., SF₆) and conservative tracer (e.g., NaCl or NaBr) – At the same time and location, add inert gas (to account for diffusion) and conservative tracer (to account for groundwater inputs) to the stream. Rate of either tracer addition depends on stream flow but must NOT change once the experiment begin or the loss rate calculations will be inaccurate.
 - a. SF₆ Addition:
 - 1) Streams with flows of <200 L/s (0.05 – 0.2 m³/s), receive approximately 100 mL/min.
 - 2) Most streams <1000 L/s (<1 m³/s) can also receive 100 mL/min. In more turbulent streams you may need to Increase gas flow rate, as necessary (**Table 8**) (i.e., if lab analysis can't detect gas at the bottom of the reach, Science will notify domains).
 - 3) In a larger (>1000 L/s), steep, and turbulent streams, you may need increase gas flow to 248 ml/min (scale reading 40), so that the SF6 is still detectable at station 4. Please contact Science if you have questions.

Table 8. Psi to mL/min conversion chart.

| Scale Reading | Glass Flow mL/min |
|---------------|-------------------|
| 50 | 308 |
| 40 | 248 |
| 30 | 181 |
| 20 | 118 |
| 10 | 70 |

- b. Salt Addition:

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- 1) 5-15 mg Cl⁻/L NaCl above background (~10-30 μS/cm) or 0.025 – 0.05 mg Br/L of stream discharge.
- 2) If pump rates > 500 ml/min you will need to adjust tubing to accommodate higher flows rates. 3/8" I.D. tubing or greater is required for flows higher than 500 ml/min and 1/2" I.D. tubing or greater is required for flows higher than 1200 ml/min.
- 3) If stream flows are >2000 L/s, discuss with NEON Science, as it may be too challenging to get enough conservative tracer into the stream. Bouts may need to be rescheduled for when flows are <2000 L/s.
4. Collect conservative tracer injectate sample.
5. Collect Plateau Samples – While injection continues at a constant flow rate, take samples starting at the most upstream station (Station 1) after the furthest downstream station (Station 4) reaches plateau of conservative tracer (e.g., NaCl).
 - a. Collect five 40 mL water samples at each of the 4 sampling stations into pre-labeled syringes – each syringe will provide a gas and water sample. Sample from **upstream to downstream**.
 - b. Record stream temperature, specific conductivity, and time when samples are taken at each of the 4 sampling stations.
6. Stop tracer injections.
7. Process samples (pull in air and shake for 5 minutes) at a base camp away from stream and upwind of the injection site to limit potential gas contamination. From each syringe collect a gas and water sample.
8. Store samples appropriately.
 - a. Gas samples → Sealed in gas vials.
 - b. Water tracer samples → Tightly sealed in labeled 60-mL HDPE bottles.
9. Measure wetted widths at 30 evenly spaced locations along the stream reach (between Station 1 and Station 4). It is recommended this be completed at the end of the experiment, so as not to stir up stream bottom.
10. Collect loggers from station 1 and 4
11. Clean FMI pump

| | | |
|--|--------------------|------------------|

SOP C Preparation

C.1 The Day Before

1. Test pump before going to field (Pump should be connected to an 8 Volt battery).
 - a. Lubricate pump prior to use by placing a small dab of high-grade machine oil on the piston drive pin immediately before inserting into the radial bearing (Figure 2b).
 - b. Ensure pump has been assembled correctly:
 - 1) If piston has been withdrawn more than 2 inches from the cylinder (Figure 2a), or removed completely from the pump head (Figure 2b), you **MUST** take special precautions before reassembling pump or **Lip Seals will be damaged. See Appendix E for correct assembly instructions.**
 - 2) Tighten thumbscrew (Figure 2a) to hold drive carrier in place.

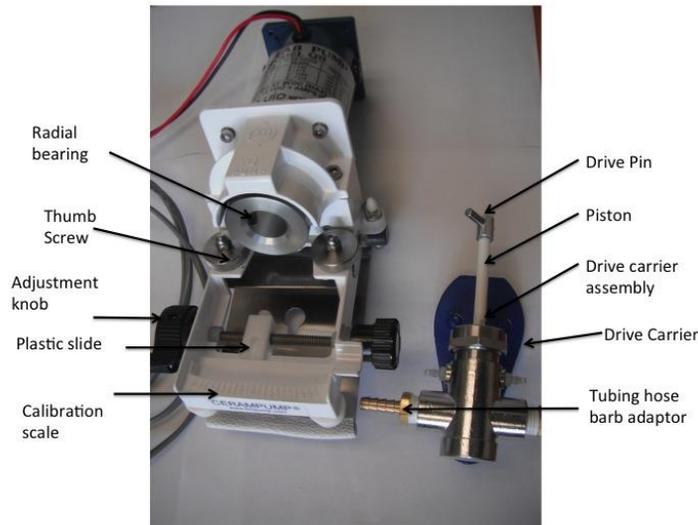

Figure 2. Fluid metering pump a) Components of pump drive (left) and b) pump head (right)

2. Test Pump: Test pump by placing it on the rim of a 5-gallon bucket with inlet and outlet tubing ends placed in the bucket containing tap water. Connect the pump to a battery and run the pump to make sure everything is connected and working properly. Look for leaks.
 - a. Using the adjustment knob and the calibration scale, adjust rate to achieve the desired flow rate. If the carrier does not move when adjustment knob is turned, the knob is not properly attached to the plastic slide.
 - 1) The angle of the drive shaft cylinder with respect to zero (center) on the calibration scale controls the magnitude and direction of flow. Ex) If cylinder is pointed to left at 10 on the scale, the fluid will be passed from the right port to the left port at 100% of the maximum rated volume. If the cylinder is pointed to the 5 on the right

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

calibration scale, the fluid will be passed from the left to the right port at 50% of the maximum flow rate.

- **NOTE:** 200 mL/min is a very common flow rate for most NEON streams. The maximum pump flow rates will be 1296 ml/min (Q2 piston code). Minimum pump rate for this pump is 129.6 ml/min.
- 2) If you need to adjust flow rate, loosen the two thumbscrews slightly and use the adjustment knob as necessary. Remember that the pump flow rates are very sensitive, thus small adjustments may be all that is required. Retighten thumbscrews when adjustment is complete.
 3. Use the injection calculation spreadsheet (Figure 3) to calculate the quantity of the conservative tracer (NaCl) you will need to add to the bucket/carboy. Note: If not able to use salt as a continuous tracer, see Site-Specific Information (Appendix G). Tracer addition needs to be large enough to detect the tracer at the most downstream sampling station and will vary by location and time as discharge and background conductivity values change. Aim for a 5-15 mg/L increase in Cl⁻ (10 – 30 μS /cm), with 40 - 50% saturation of the conservative tracer (absolute maximum 75% saturation). In low conductivity streams (<100 μS /cm), an increase of 5- 10 μS/cm will be sufficient to detect a change. The calculation spreadsheet (Figure 3) is located in the Reaeration Data sheet excel file (RD[05]).
 - a. If the spreadsheet returns an error, you need to go back and adjust the parameters in the yellow squares. The error indicates that you cannot dissolve enough salt to make the concentration solution you are suggesting. To fix the error, you will need to use a larger volume bucket so you can dissolve more salt and/or increase the pump rate (if you are pumping faster you need less salt because you are adding it at a faster rate). Keep in mind that if you increase the pump rate, there is less time for the stream to come to plateau and finish the sampling before the bucket is empty.
 - b. Ensure you do not pump so fast that you run out of solution before the end of the experiment. Use the spreadsheet to determine the ‘Max injection time’ and aim to end the experiments 15 minutes before so you do not run the pump dry.

Figure 3. Example of injection calculation worksheet for NaCl. Modified from LINX II. The squares in yellow are the ones that you are free to adjust based on your stream conditions. Start by entering your estimated stream Q. In this example the, we are targeting to increase the stream conductivity by 7 mg/L (~ 14 μS/cm). Our stream flow is 60 L/s and we want to release for an hour and mix our salt into 17 L of water. If we have a release rate of 200 mL/min, the spreadsheet calculates that we can actually pump for 1.4 hours before we are out of solution. In order to make up this salt solution, we need to weight out 3531 g of NaCl.

4. The amount of salt required is a product of the target enrichment, the estimated stream flow and the injection rate.
 - a. Once stream discharge rating curves are available for a site, you may use the current pressure transducer data and discharge rating curve to estimate current discharge, used in the calculation spreadsheet.
 - b. The below equation is the equation used in the spreadsheet to calculate the amount of NaCl needed for the continuous injection.

$$\begin{aligned}
 \text{Amt of NaCl (g)} &= (((\text{Cl}^- \text{ target enrichment (mg/L)} * \text{Stream Q (L/s)} \\
 &\quad * 60) / (\text{injection rate (mL/min)})) * 58.44247 / 35.4527) \\
 &\quad * \text{Volume of Tracer Solution (L)}
 \end{aligned}$$

5. Weigh out the amount calculated and dissolve the salt in tap water in a small container, as needed (i.e., a liter bottle or a 4-L jug). Ensure the tracer is completely dissolved. If you estimate your discharge for calculations, take extra salt into the field with you in case your estimates were low and you need more salt.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- a. Scales used in the field are considerably less accurate than those used in the lab- Rather than weigh salt in the field. Pre-weight discrete amounts of the conservative tracer in the lab so can adjust conservative tracer mass in the field as needed.
6. **Record** the amount of salt added in the Reaeration mobile application.
7. Confirm that you have newly evacuated gas vials from a gas laboratory. Vials should be < 2 months old and should not have any water in them.
8. Ensure stopcocks for syringes are intact, these can develop hairline fractures over time.
9. Charge 8 V batteries OVERNIGHT. The pump manufacturer suggests using 8V batteries with the pump. You may need to wire four 8 V batteries in parallel in order to maintain pump speeds throughout the experiment. See pump trouble shooting tips (D.4 Troubleshooting). 12 V batteries are not suggested because they can decrease the life of the pump.
10. Check the battery life of the handheld and logging probes. Calibrate the conductivity handheld meter (make sure entire probe, including the 2 black holes at the top, is completely immersed). Logging conductivity probes do not need to be calibrated, but should be validated against hand held measurements occasionally. Submit a trouble ticket if probes are not reading correctly.
 - a. Set logging probes to begin logging (10 second intervals) on the reaeration field day. Ensure temperature is set to Celsius. Note: Probes should be logging prior to placing them in the stream. You can set the loggers to start on a delay, but we want them logging before the injection starts so that we can get a good background reading. See user manual for calibration and usage instructions. Update firmware, as needed.
 - b. If you are completing a slug in the spring and your site has very fast travel times (<10 min), set the HOBOS to log every second.
11. Label all gas vials and conservative tracer bottles (60 mL HDPE) with a human-readable label and apply Type I barcodes.
 - a. Gas Vials (20):
 - 1) Sample IDs: **SITE.vialID.YYYYMMDD.GAS**,
where site is 4 letter SITE code, vialID corresponds to 2-digit syringe number (01-20), and date (YYYYMMDD). (Ex. Red Butte Creek, Station 2, Sample 06 on May 14 2014 is REDB.06.20140514.GAS).

- 2) To apply labels, remove submerged vials from storage container, dry and apply:
 - a) Human-readable label with sample ID. On each vial, apply a label parallel to long axis and cover with clear packing tape to prevent coming off when stored in water. Wrap the tape completely around the vial, perpendicular to the label. The ends of the tape should overlap to keep the tape from coming unstuck. You may need two rows of tape.

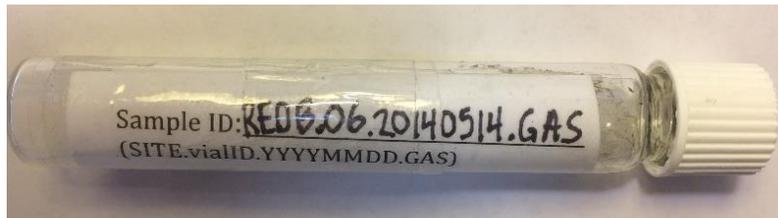

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- b) Type 1 barcode label on top of the tape and on the opposite side as the sample ID label. Orient the barcode label parallel to long axis of the vial and allow the adhesive to cure for 30 minutes.
- (1) Workflow tip: Write the vialID number on the bottom of each vial with permanent maker. This will help you quickly locate the correct vial during sample processing (Figure 4).

Figure 4. vialID number written on the bottom of each vial to help locate vials quickly.

- (2) Return vials upside down in the storage container so the cap is submerged for transport to field site.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

Figure 5. Example of tracer gas vial labels.

- b. Conservative Tracer (TCR): Label 25 sixty (60) mL plastic bottles.
 - 1) SampleID: **SITE.bottleID.YYYYMMDD.TCR**
(Ex. Red Butte Creek, Station 2, Sample 06 on May 14 2014 is REDB.06.20140514.TCR).
 - a) Bottle IDs are **2-digit codes**: B1-B4 – Background Station 1 – Station 4, 00-Injectate, 01-05 indicates the five samples taken at Station 1, 06-10 indicates the five samples taken at Station 2, 11-15 samples at Station 3, 16-20 samples at Station 4 (Table 9). The bottle IDs 01-20 correspond to the field syringe IDs.
 - b) For the injectate sample: Make a dot on the label with a red permanent marker to indicate to the lab this is an injectate sample.

Table 9. List of bottle ID numbers for the conservative tracer

| Sample Station | Bottle ID |
|----------------|---|
| Background | B1-B4: B Station # (1 – 4, where 1 is Station 1). |
| Injectate | 00 (make red dot on label with permanent marker) |
| Station 1 | 01-05 |
| Station 2 | 06-10 |
| Station 3 | 11-15 |
| Station 4 | 16-20 |

SOP D Sample Collection in the Field

In the field, fill out the General AQU Field Metadata Fulcrum App on tablet before collecting samples.

D.1 Background Sampling

1. First, visit each of the four sampling stations (Figure 7), and at each station record four conductivity measurements from the stream thalweg (i.e. the main flow of the stream), for a total of 16 conductivity measurements (See RD[05], Field Data Sheets). Make sure the hand-held conductivity meter is set on the temperature-corrected setting and units (SPC, uS/cm). Wait for the meter to adjust to the stream temperature for more accurate conductivity measurements.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- a. **NOTE:** The conductivity sensor is located at the top of the probe where the two black holes are located, so the **ENTIRE** probe must be underwater to get the measurements. Ensure the water is deep enough to cover the entire probe.

Figure 6. Conductivity sensor is located at the top of the probe. Ensure the entire probe is in the water for accurate readings.

- b. Jiggle the probe to make sure no air bubbles are next to the conductivity sensor (2 black holes) so the conductivity measures correctly.

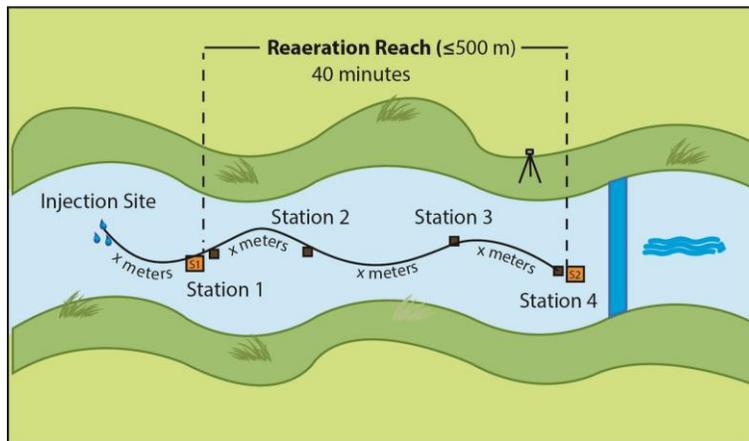

Figure 7. Schematic of stream reach with injection site and four downstream sampling stations. Travel time between Station 1 and 4 should be ~40 minutes. Note that Reaeration station 1 is co-located with Sensor set 1 and Reaeration station 4 is co-located with sensor set 2.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

2. Collect background sample from the thalweg at each station using the corresponding background syringes.
 - a. Triple rinse syringe with stream water
 - b. Fill syringe with 60 mL stream water
 - c. Attach 30 mm diameter, 0.7 um pore size filter to syringe
 - d. Triple rinse, with a ~ 5 mLs of filtered water from the syringe, the corresponding pre-labeled 60 mL bottle with filtered stream water then fill sample bottle with filtered stream water for a background Cl⁻ sample. Collect a minimum of 40 mL of sample, as you would all other salt samples.
 - 1) BottleID = B1 at Station 1; B2 at Station 2; B3 at Station 3; and B4 at Station 4
3. Mark and label each station with flagging tape, if necessary, to help find the sampling stations during the injection.
4. Place logging conductivity probes in the thalweg at Station 1 and Station 4. Since we are measuring reaeration rates between our sensor sets, **conductivity probes must be place at same transect as the sensors sets (within 0.1 m of main infrastructure)**.
 - a. Probes should already be logging at 10 second (or 1 second) intervals.
 - b. Probes must be suspended in water column, if water depth allows. You can suspend them from the stream infrastructure, temporarily installed rebar, etc.
 - c. Remember that the conductivity sensor is located at the opposite end of the probe removable cap, thus the entire sensor must be submerged.

D.2 In Field (plan 3-4 hours)

1. Fill a 5-gallon bucket/carboy with stream water and stir in the prepared concentrated salt solution. This will allow some time for the water to warm while you get the rest of the set-up ready and will allow any undissolved salt to dissolve more easily. You may need to increase the size of your bucket if the stream is large or flows are very high. **Record** the volume of the saltwater solution on the tablet or injection data sheet to the nearest 0.5 L (RD[05]). You may want to mark on the bucket the volume line you will be using to make filling the bucket easier.
2. Set up the bucket/carboy, tubing, battery, and pump on a level surface at the injection site (Figure 8). If a level surface on the bank is not adequate, place pump set-up on a bridge or plank laid across the stream.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

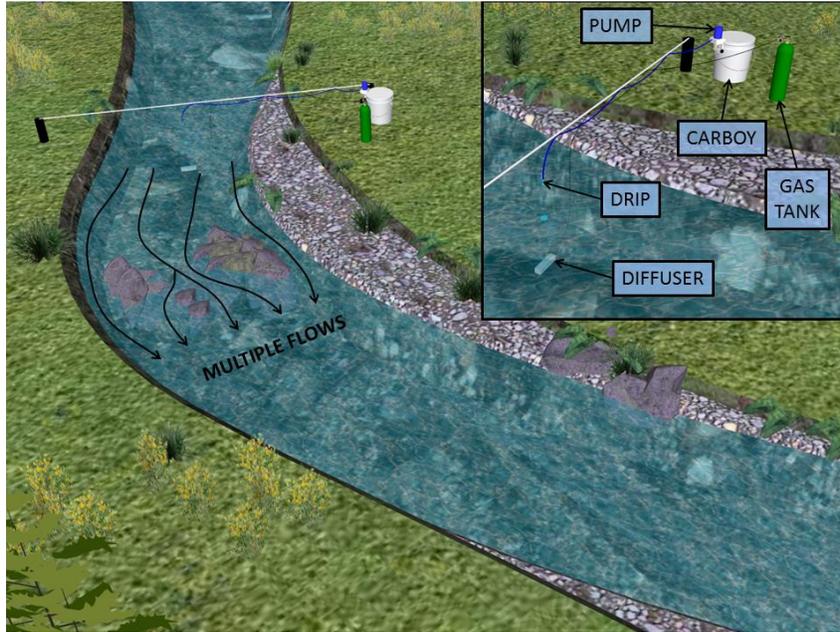

Figure 8. Field setup of the injection site with conservative tracer and inert gas

3. Pump setup:

- a. Mount pump upright for best performance. Pump can easily be mounted on the wall of a 5-gallon bucket (Figure 9). Note that as saltwater level lowers in the bucket it can get top heavy with the pump and fall over, take precautions to prevent this. (Hanging the pump INSIDE a second, empty bucket is a good option).
- b. Place the pump inlet tube into the container with the saltwater solution. Ensure the end of the tubing remains in the solution (e.g., weight the end of the tube or use a binder clip to secure the tube to the side of the 5-gallon bucket so that the tubing end remains in the solution).
 - 1) The end of the tube should be near the bottom of the bucket so that as the tracer level draws down throughout the injection, the tubing will remain in the solution. Pumping air through the pump will damage it.
 - 2) If the stream water has a lot of particulates, you may want to screen the inlet end of your tubing or bring additional water with you from the lab. You do not want to run particulates through the pump.
- c. Attach the pump electrical wires to the battery (Red to Red and Black to Black).

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

Figure 9. Mounting of the pump on the conservative tracer bucket

4. Ensure you have a way to set-up pump tubing so that the end of the tubing is located a few inches above the water surface.
 - a. **DO NOT** put the tubing into the stream because it will change the pump rate.
 - b. Attach the tubing to something stable, such as a piece of rebar, temporarily pounded into the streambed or a tree above the stream.
 - c. Make sure the tubing will INJECT (i.e., Drip) INTO THE THALWEG so the solution will mix as quickly as possible with the stream water (Figure 8).
5. **Pump Calibration:** Allow the pump to run, with the end of the outlet tube feeding back into the bucket/carboy for several minutes to allow for the tubing to fill with the injection solution. Calibrate the pump using a stopwatch and graduated cylinder to the desired pump rate from the injection spreadsheet (Figure 3). To ensure a more accurate calibration, make sure to test the injection at the stream and at the same height that the tubing will be placed during the injection. For example, if during the injection the tubing will be placed 2 feet above the stream surface, then hold the tubing 2 feet above the stream surface during calibration. It is best to calibrate the pump at the exact location
 - a. NOTE: This step may take several minutes, but it is extremely important to get the correct pump rate.
 - 1) Flow rates should be measured at 30 seconds or 1 minute intervals. Measuring flow for 1 minute will be more accurate than measuring for 30 seconds.
 - b. Every time you test the rate, pour the injectate back into the bucket/carboy and return the outlet tubing to the bucket. DO NOT dispose of injectate solution.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- c. Record the actual (what was measured in the cylinder) pump rate on the data sheet as “Start Pump Rate” (See RD[05], Field Data Sheets).
- d. Place the outlet end of the tubing back into the bucket. Keep the pump running while you continue setting up the experiment.

- 6. Collect a 60-mL bottle of conservative tracer injection solution into the pre-labeled injectate bottle (Bottle ID – ‘00’). This is an **EXTREMELY IMPORTANT** step so that we know the exact concentration of the solution we added to the stream.
 - a. Triple rinse corresponding syringe with conservative tracer injection solution.
 - b. Attach 30 mm diameter, 0.7 um pore size to syringe and triple rinse (~ 5 mL per rinse) corresponding 60 mL pre-labeled sample bottle with filtered tracer solution to remove any particulates that could clog the analyzer. Collect a minimum of 40 mL of sample, as you would all other salt samples.
 - c. Make sure there is a red dot on the label to indicate to the lab this is an injectate sample.
 - d. Enter data into Fulcrum and scan sample.

7. **Gas Injection Set-up:**

- a. At the injection site, set-up the SF₆ gas tank, regulator and flow meter (Figure 10).
 - 1) Attach the regulator to the gas tank using the appropriate size wrench (1-1/8-inch wrench). Do NOT use Teflon Tape on the fitting that goes into the tank. (Note: Teflon can be used on all fittings associated with the regulator, except the one that goes into the tank.)
 - 2) Use gas-impermeable (e.g., Tygon) tubing to connect the SF₆ gas tank and regulator to the gas flow meter. Make sure that the tube running from the gas tank is connected to the **BOTTOM** connector of the flowmeter.
 - 3) Use gas-impermeable (e.g., Tygon) tubing to connect the **TOP** of the flowmeter to the diffuser (air stone). The tank can lie horizontal on the ground.
 - 4) Place diffuser in water at the same location in the stream as the conservative tracer injection (Figure 8). Make sure diffuser is completely submerged and secured so that it will remain underwater and in the same location.
 - 5) Ensure the gas flowmeter is **vertical**. The flowmeter must remain upright for the best performance. Do NOT lay it on the ground.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

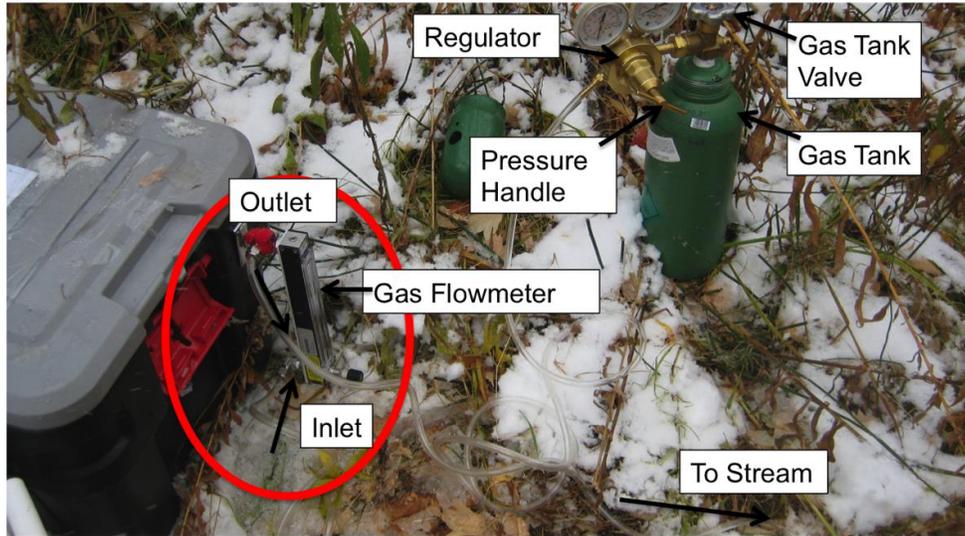

Figure 10. Gas tank, regulator, and flowmeter field setup

- 6) Connect all parts of the gas set-up before opening the main valve on the tank.
 - 7) Turn regulator pressure handle completely to the closed position on the regulator. This will close the regulator valve and keep your gas from blowing through before you are ready.
 - 8) Open the gas tank valve.
 - 9) Slowly turn the regulator pressure handle to the left to allow gas to flow to the flowmeter.
 - 10) Set the regulator at 12 psi.
 - 11) On the flowmeter, turn the valve so that it reads approximately 35 psi. Only adjust the psi settings if your stream flows are >1000 L/s and your stream is very high-gradient and turbulent (i.e. lots of reaeration) (Table 8).
 - 12) Make sure you see little bubbles coming out of the diffuser (air stone). If the bubbles are not visible due to reflections or ripples on the surface of the water verify bubbles in a bucket of still water.
8. Once you have calibrated the pump and made sure the gas set-up is working and not leaking, start the stream injection by securing the pump tubing above the stream surface at the **same time** as you turn on the gas injection. NOTE: If using NaBr, you will also need to do a salt slug so that you can know when to sample and we can estimate travel times. See Appendix G: Site-Specific Information.

NOTE: After injection into stream begins, **do NOT change the flow rate of the gas or the conservative tracer.**

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

9. Record the start time on the tablet or Reaeration Field Data Sheet (RD[05]).
10. Spend a few more minutes at the injection site making sure the salt and gas injections are working properly.
11. **Monitor for plateau:** Walk to the MOST DOWNSTREAM station (with your travel time in mind, make sure you arrive in time to take rising limb conductivity readings). You will need a hand-held conductivity meter.
12. Once at the most downstream station, place the handheld conductivity meter in the stream, just downstream of the Station 4 logger. Make sure the probe is fully submerged in the main flow. Do not put the probe in a side pool.
 - a. **NOTE:** The conductivity sensor is located at the top of the probe where the two black holes are located, so the **ENTIRE** probe must be underwater to get the measurements. Ensure the water is deep enough to cover the entire probe.
 - b. Jiggle the probe to make sure no air bubbles are next to the conductivity sensor (2 black holes) so the conductivity measures correctly.
13. Continue to observe conductivity until the stream has reached plateau (when salt concentration/conductivity measurement is no longer rising during continuous injection or when stream conductivity has returned to near background conditions if using salt slug). Sampling must not begin until the stream has reached plateau at the MOST DOWNSTREAM station, usually 30 minutes to an hour during low flows and will be faster during high flows.
14. Once the most DOWNSTREAM station has reached plateau, start sampling at the most UPSTREAM station (i.e., Station 1, the station closest to the injection site) and work downstream (Figure 7). The idea is that you are following a parcel of water as it moves downstream.
 - a. When travel times are very slow, you will sample from Station 1 to station 4, but at a faster rate than the travel time. That's ok, as long as the stream is at plateau. For example, if the travel time of your stream is 40 minutes, and the you sample station 1 through station 4 in 10 minutes, that is OK, provided the stream is at plateau and that you sample from Station 1 to Station 4.
15. At Station 1, record 5 temperature-corrected conductivity measurements across the main flowing section of the stream. You only need to do this step at Station 1 to ensure the NaCl tracer is mixed across the stream (See RD[05], Field Data Sheets).
 - a. If stream is not mixed by station 1, you should move your injection station further upstream to allow for more stream length for mixing to occur.
 - b. For NaBr additions, you only need to record 1 conductivity measurement in the thalweg.
16. Take 5 syringe samples **in the thalweg** at each sampling stations. You may need to get into the stream to do this. Only step into the stream at designated sampling stations and do your best to not disturb the sediment as you walk. If you do kick up benthic sediments, wait for the area to clear before sampling. ALWAYS take samples upstream of where you are standing.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

17. RINSE: Place the syringe tip (with 1-way stopper attached and turned to open; Figure 11) into the stream so that you are sampling the water ~10 cm under the surface of the water. If water column is very shallow (< 10 cm), sample in the middle of the water column being careful not to pull in benthic sediment when sampling. Pull in ~20 mL water and remove syringe from stream. Rinse the syringe by pulling the stopper all the way back (without removing it) and shake. Expel the rinse water downstream or onto the bank.
18. Rinse 2 more times

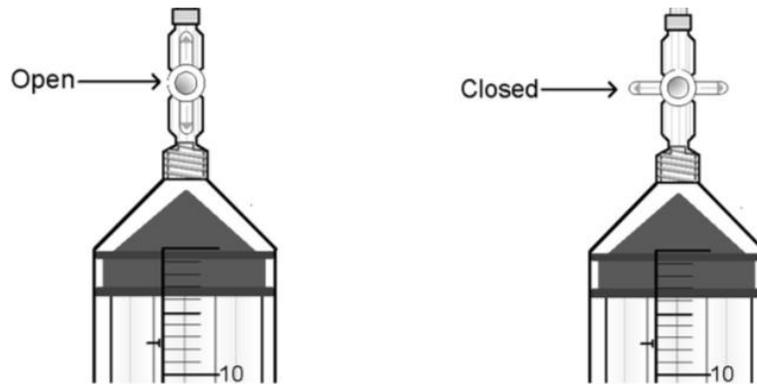

Figure 11. Example of a syringe and stopcock in the "open" and "closed" positions

19. SAMPLE: Put the syringe tip back into the water in the thalweg, below the surface, and pull the plunger until the syringe is completely full. Remove the syringe and tap the sides of the syringe firmly with your hand/fingers to remove the air bubbles. EXPEL water, leaving approximately 1 mL in the syringe, which will help reduce air intake on the next sampling. Put the syringe back in the water, expel the final 1 mL of aerated water below the stream surface, and slowly fill to the 40-mL mark, being careful not to entrain any air bubbles (Figure 12). Tip: You can put the entire syringe in the stream, horizontal to stream bed, to reduce air intake. Immediately turn the 1-way stopper to the closed position before removing the syringe from the stream (Figure 11). Take 5 separate syringe samples all within the main flow of water. Place the syringe in a small cooler to help maintain stream temperature at time of collection.

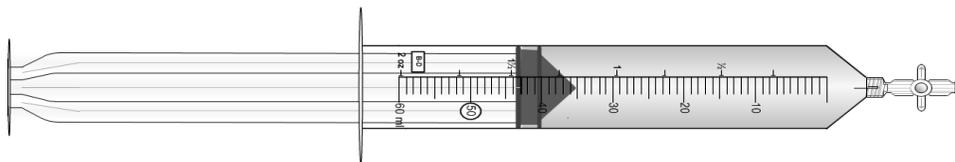

Figure 12. A syringe with a 40-mL water sample

20. At each station (for all injection types), record the time, 5 syringe IDs, water temperature, and conductivity (5 readings at Station 1) on the tablet or reaeration spreadsheet (See RD[05], Field Data Sheets).

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

21. REPEAT (Steps 17-20) for each sampling station, always working from upstream to downstream. When walking between stations, do not walk in the stream.

NOTE: If multiple people are simultaneously collecting samples at the same station, make sure they are standing at the same distance from the injection site (i.e. side by side, not upstream or downstream from one another).

22. Return to the Injection Site. Test and Record the 'End Pump Rate' and time on the tablet or field data collection sheet (See RD[05], Field Data Sheets).
23. END INJECTION: Turn off Gas and Pump.
24. If you did not already, SAVE some conservative tracer solution in a 60-mL bottle, labeled with Sample ID (SITE.00.YYYYMMDD.TCR),
- Make sure there is a red dot on the label to indicate to the lab this is an injectate sample.
 - Store sample in its own resealable plastic bag to reduce contamination. This will also ensure the lab knows it is an injectate sample, and will need to be diluted.
25. BREAK DOWN the gas and NaCl injection set-ups.
26. RINSE INJECTION EQUIPMENT(This can be done back at the DSF)
- Return any remaining conservative tracer solution to the lab, via the bucket or the plastic jugs used to transport the concentrated solution to the field. The salt solution will need to be disposed of in the lab, so as not to add too much salt to the stream.
 - Fill a bucket/carboy with fresh stream water and run the pump for a minimum of 30 minutes to flush the NaCl from the pump equipment.
27. Rinse the outside of the pump in stream water to remove all salt from the pump. Ensure any parts that were touching the salt solution are thoroughly rinsed.
28. Collect wetted widths after samples have been collected, so as not to stir up samples and impact measurements: 30 stream wetted width measurements approximately evenly spaced throughout the reach, between Station 1 (Sensor Set 1) and Station 4 (Sensor set 2) (e.g., 10 wetted width measurements between station 1 and 2, 10 measurements between station 2 and 3 and 10 measurements between station 3 and 4). Measure the full wetted width of the stream, including under cut banks.
- When measuring wetted widths, the meter tape should be parallel to the ground, perpendicular to the banks, and as close to the stream as possible to get accurate wetted width measurements.
 - If available, a laser rangefinder can be used to measure wetted widths provided stream is greater than 2 m wide, on average. This can be done during the salt slug, as long as you are not getting in the stream. Note, that the laser range finder is not as accurate as a meter tape, thus the meter tape is the preferred measuring tool.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

29. COLLECT logging conductivity meters LAST (after sample processing, if processing in the field). This should be the **very last** thing you do before leaving the site. We want to get as much of the declining salt curve as possible.
- See Additional Directions/Notes for additional information on downloading HOBO data files.

D.3 Sample Processing

- Samples should be processed immediately after sample collection. Syringe walls are gas permeable so gas will begin to exchange across the syringe wall, impacting SF₆ concentrations.
- Away from stream, where there will be no contamination in the air from the injection, such as upstream and upwind, open stopcock and draw the plunger to the 60 mL, so you have 40 mL of water and 20 mL of air (Figure 13). Close stopcock and leave stopcock attached to syringe at all times. VERY IMPORTANT: To be consistent, be sure to pull the plunger from the 40 to the 60-mL mark (Figure 13).

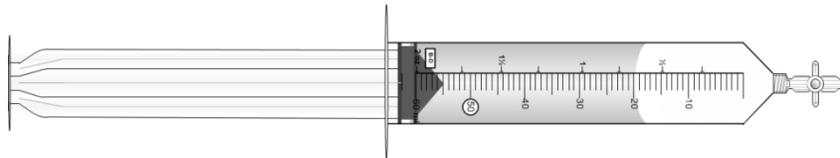

Figure 13. A syringe with 40 mL of water and 20 mL of air

- SHAKE:** Once samples have been collected from ALL stations, shake each syringe for 5 minutes to equilibrate the air and SF₆. To save time, shake multiple syringes at once.
- After shaking, place needle with needle cover still attached on 1-way stopcock. Once needle is attached, remove the plastic covering. Holding the syringe upright, open the stopcock (Figure 14a) and push a small amount of air (~0.5 mLs) through the needle to purge the air in needle.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

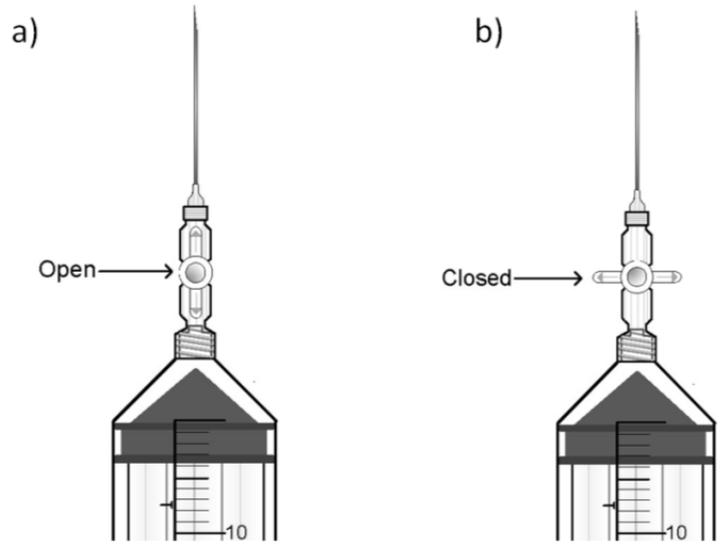

Figure 14. Example of a syringe with a stopcock with attached needles in the a) "open" and b) "closed" positions

5. With stopcock still 'open' and syringe held upright, insert the needle through the rubber septum of the gas vial (**Figure 15**) and push gas into the vial. Properly evacuated vials will automatically suck in the gas.
 - a. If vial does not suck up air it is not properly evacuated. Remove the needle from the vial and use one of your backup vials.
6. Push as much gas in as possible without injecting the water sample in the vial (~18 mLs of gas).
 - a. Make sure to OVER-PRESSURIZE THE VIALS to prevent gas from leaking into the vials. You do not need to record the volume of gas injected into the vial, as long as the vial is over-pressurized.
7. While continuing to press up on the plunger, remove the syringe needle from the vial, without closing the 1-way stopcock. Closing the one-way stopcock will cause sample to be sucked out of the vial, resulting in gas sample loss.
8. You may re-use the same needle across a single station per SITE on a sampling day as long as the needle remains structurally sound and the needle is purged between samples to remove any non-sampled gas. If needle bends or breaks, use a new needle. Discard needles in a sharps container.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

Figure 15. Insertion of the needle into a gas vial through the rubber septum.

9. SAMPLE CONSERVATIVE TRACER: Cover needle if reusing at same station, otherwise discard in Sharps container. Remove the 1-way stopcock. Hold syringe upright and expel remaining air from the syringe (Pushing air through the filter can cause the filter to rupture). Attach a 30 mm/ 0.7 μ m filter capsule onto the syringe. Rinse the 60-mL bottle with 5 mLs of filtered sample twice. Filter the remaining syringe sample (~30 mLs) into the bottle. Be sure the bottle is labeled with sampleID (site ID.bottleID.YYYYMMDD.TCR). BottleID should match the syringe IDs. Repeat for all syringes.
10. Scan barcodes in the mobile app as each sample is collected.
 - a. If available, scan the barcode label with the tablet (Figure 16).
 - b. Ensure that the human-readable sample ID matches the sample ID generated by the mobile app.
11. DISCARD filter and replace stopcock on each syringe. Note: you may re-use the same filter across a single station per SITE on a sampling day, as long as the filter is not clogged and the filter is rinsed between samples with the new sample water.

D.4 Troubleshooting

1. Diffuser:
 - a. If no bubbles are coming out of diffuser plate, then check 1) tank is turned on and regulator is open and 2) all tubing connections. Apply SNOOP (or soapy water) to the tube connections and watch for bubbles, which indicate a gas leak.
 - b. Ensure the connection between the tubing and the air-stone is secure so gas isn't escaping before entering the diffuser.
 - c. If pores seem clogged or filled with algae, clean diffuser using hard-bristled brush or 10% bleach solution.
2. Pump: If the pump is not working or is not working correctly (Note, if the pump fails mid-experiment and the stream has not yet reached plateau, or in the NaBr, the peak has not returned to background levels, then you will need to start over once the pump issue is resolved or reschedule):
 - a. Check battery charge and try another battery. It is always a good precaution to bring an extra battery with you to the field with you even if it is not fully charged. If changing the battery changes the pump rate, it is a battery problem. If changing the battery doesn't affect the rate, check to make sure all wires are well connected.
 - 1) If the pump is dying before experiment ends, try hooking up four 8V batteries in parallel. To wire in parallel, you connect all of the positive terminals together and then all the negative terminals together, using terminal blocks to make this easier. Then, hook up the positive lead of the pump to the positive terminal block and the negative lead to the negative block (**Figure 17**). It is encouraged that you use the multi-battery solution proactively to prevent pump issues from occurring, even if you have not had issues to date.

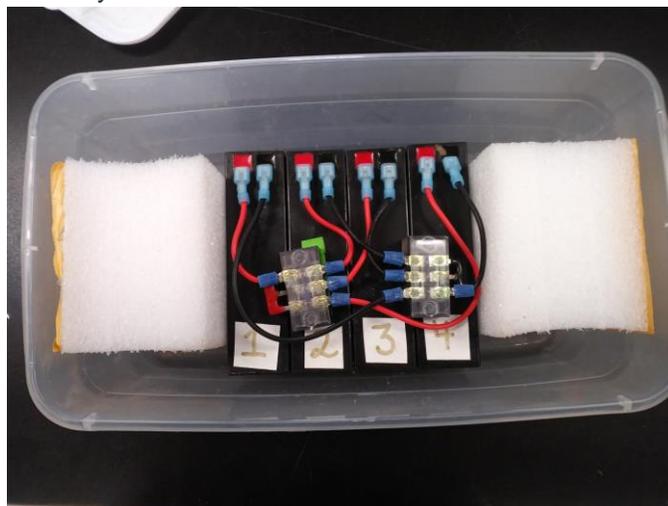

Figure 17. 8V batteries wired in parallel.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

- b. Ensure pump thumbscrews are securely tightened.
 - c. Check pump connection to battery to make sure they are secure.
 - d. If the pump has seized you can crank the top piston slightly to unseized it.
 - e. If the pump has seized, you can gravity feed DI into the upper “lubricating” inlet using 1/8” ID tubing while running the pump.
 - f. Soak piston in warm DI for a few hours.
 - g. Refer to pump user’s manual.
3. Conductivity probe: If hand-held conductivity probe is not measuring properly:
- a. Jiggle the probe to make sure no air bubbles are next to the conductivity sensor (2 black holes).
 - b. Make sure entire probe, including the 2 black holes at the top, is completely immersed.

D.5 Sample Preservation

1. Gas Samples:

- a. Gas samples should be stored upside down in containers with water so the vial caps are submerged in water. This reduces the risk of sample loss. **VERY IMPORTANT:** Gas samples should be stored away from heat source (room temperature is fine), such as in a cooler.
 - 1) Do not put stream water into the vial storage container. Tap water and DI water are fine.

2. Chloride Samples:

- a. There are no preservation requirements for chloride samples.
- b. Samples can be stored at room temperature.
- c. Store injectate sample (labeled with red dot) in its own resealable plastic bag.

D.6 Ending the Sampling Day

1. Refreshing the sampling kit

- a. Restock the sampling kit with newly evacuated gas vials, new chloride sampling bottles (with new labels), syringe filters, needles, etc.

2. Equipment maintenance, cleaning and storage

a. Pump:

- 1) Run clean water (this can be stream water) through the pump and tubing for 30-60 minutes to rinse salt water from equipment. You can do this in the field while you complete sample processing, or in the lab later that day.
 - a) Fill bucket approximately half full with clean water.

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

- b) Place the intake and outtake tubing into the clean water and then you can run the pump without fear of the reservoir going dry.
 - 2) Rinse of external parts of the pump with freshwater to remove any salt solution.
 - 3) Upon returning to Domain support facility:
 - a) Soak piston in warm DI water for a few hours
 - b) Allow pump to air dry before storage
 - b. Place clean and dried pump in plastic storage bag, before placing in plastic storage tote with foam. Empty all water from tubing before storage.
 - c. Charge batteries.
- 3. Track SF6 volume and ensure you get extra SF6 on hand when needed. Record cylinder PSI on cylinder before and after bouts, so you know how much you use per bout and can order more/refill tank, when necessary.
- 4. Refill SF6 canister when empty: SF6 canisters are re-usable.
 - a. Work with your Safety Officer.
 - b. To send canisters with valve cover back to the supplier to be refilled, gas tanks **MUST** be empty, so that the container can be shipped as non-hazardous material.
 - c. Tape over the canister label with masking tape and write "Empty" on tape
 - d. Ship in double-walled cardboard boxes due to weight of canisters. You can re-use the box it was shipped to the domain in.
 - e. Note: If the tank is **NOT EMPTY**, it needs to be shipped as hazardous material in **new**, double-walled box, 275 lb. test.

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

SOP E Data Entry and Verification

Mobile applications are the preferred mechanism for data entry. Data should be entered into the protocol-specific application as they are being collected, whenever possible, to minimize data transcription and improve data quality. For detailed instructions on protocol specific data entry into mobile devices, see the NEON Internal Sampling Support Library (SSL). Mobile devices should be synced at the end of each field day, where possible; alternatively, devices should be synced immediately upon return to the Domain Support Facility.

Workflow Tip: Set the tablet to ‘Wet Mode’ and use a handheld scanner for rapid entry of barcodes into the tablet.

However, given the potential for mobile devices to fail under field conditions, it is imperative that paper datasheets are always available to record data. Paper datasheets should be carried along with the mobile devices to sampling locations at all times. As a best practice, field data collected on paper datasheets should be digitally transcribed within 7 days of collection or the end of a sampling bout (where applicable). However, given logistical constraints, the maximum timeline for entering data is within 14 days of collection or the end of a sampling bout (where applicable). See RD[04] for complete instructions regarding manual data transcription.

E.1 Calculations and Data Entry

Note, calculations are for informational purposes only. They will be completed at NEON HQ.

1. Discharge: Discharge can be calculated from the conductivity measurements at Station 1 and Station 4.
 - a. Background-correct conductivity measurements at Station 1 and Station 4.
 - b. Calculate Discharge as: (a) $Q = (C_{\text{salt}} * Q_{\text{salt}}) / C_{\text{station}}$, Where C_{salt} is the conservative tracer concentration (Cl^-) in the injection solution, Q_{salt} is the injection rate (in L/s) and C_{station} is the background-corrected conservative tracer concentration at the Station 4.
 - c. Station concentration can be calculated from conductivity measurements where $1 \mu\text{S}/\text{cm} = 0.5 \text{ ppm } \text{Cl}^- (\text{mg } \text{Cl}^-/\text{L})$.
2. Reach Velocity: Calculate Average Velocity of the Reach: $V = X / \text{Travel Time}$, Where X is the distance between Station 1 and Station 4, and Travel Time is the time it takes the stream to reach $\frac{1}{2}$ half height at Station 4 minus the time to reach $\frac{1}{2}$ height at Station 1.
3. Reaeration Coefficient
 - a. Plot the natural log (LN) of the RATIO of the tracer gas concentration (or GC peak area) to the background-corrected Cl^- concentration (Y-axis) by Stream Distance (X-axis) (**Figure 18**).

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

October 2010

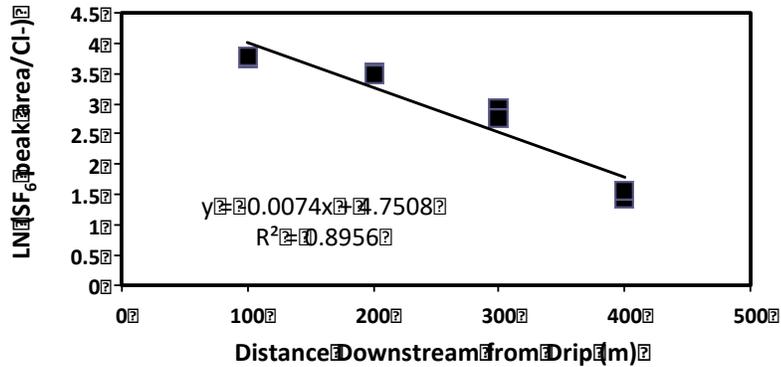

Figure 18. Example SF₆ loss rate data calculation.

- b. The slope of the line is the SF₆ loss rate (m⁻¹).
- c. Calculate Reaeration Coefficient for SF₆: Multiply SF₆ loss rate by the reach velocity (m min⁻¹) to get reaeration rate coefficient for SF₆ (K_{SF6} ; min⁻¹). Reach velocity is the distance between station 1 and 4 divided by the difference in timing of the maximum slope of the conservative tracer ascending limb at station 1 and 4.
- d. Convert Reaeration Coefficient for SF₆ to O₂ ($K_{O2} = K_{SF6} * 1.34$).
- e. Convert K₂ values from ambient stream Temp to standard temperature (T=20C)
 - 1) $K_2(T=20C) = K_2(T) * (1.0241^{(20-(Upstream(T)+Downstream(T)/2))})$
4. Develop a relationship between discharge and K_{O2}.
5. Enter data into excel file named "Reaeration Field Data." Save file in format:
 - a. Reaeration_SITE_YYYYMMDD.xls
 - b. Station ID will be 1 (top of reaeration sampling reach) or 4 (bottom of reaeration sampling reach)
6. Stop conductivity probes from logging and download conductivity probe data. Save files as:
 - a. Reaeration Conductivity logger_SITE_StationID_YYYYMMDD
 - 1) Station ID will be 1 (top of reaeration sampling reach) or 4 (bottom of reaeration sampling reach)

SOP F Sample Shipment

Information included in this SOP conveys science-based packaging, shipping, and handling requirements, not lab-specific or logistical demands. For that information, reference the CLA ‘Shipping Information to External Facilities’ document on CLA’s NEON intranet site.

F.1 Handling Hazardous Material

N/A

F.2 Supplies/Containers

1. Gas Samples
 - a. Use clear packing tape to secure labels to vials prior to shipping, if you have not done so already. Wipe excess water off vial prior to adding packing tape, and fully wrap tape around vial and labels (SampleID label). Place barcode label over the tape and scan the sample into Fulcrum.
 - b. Ship upside down in water in a watertight container, wrapped with electrical tape and placed in a 9-qt cooler (for 1 or 2 sites). Containers should be 2/3 full with water. This will allow for water expansion if freezing occurs, without breaking the gas vial. Container should be kept upright to ensure gas vial lids stay submerged in water.
 - c. Pack liquid absorbent material around container.
 - d. Fill any remaining space with regular packing material.
 - e. Complete packing slip, address shipment, and ship ground to the destination(s) specified in the CLA “Shipping Information for External Facilities” document.
2. Conservative Tracer Samples
 - a. Ship 60-mL Nalgene bottles, organized in plastic, resealable bags, in a cardboard box at room temperature.
 - 1) Ensure lab knows which sample is the injectate by:
 - a) Labeling with a red dot/permanent marker
 - b) Placing injectate sample in a separate resealable bag.
 - b. Place in a properly sized box (e.g., 9*8*4), lined with a garbage bag. Surround with absorbent packaging materials.
 - c. Complete packing slip, address shipment, and ship ground to the destination(s) specified in the CLA “Shipping Information for External Facilities” document.

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

F.3 Timelines

1. Gas Samples
 - a. Ship Ground, monthly, to gas analysis laboratory. Changes in temperature and elevation can alter the gas pressure in the gas vials. Dissolved gas samples can be sent with these samples.
2. Conservative Tracer Samples
 - a. Ship Ground, monthly, the injectate sample, the 4 background samples, and the 20 plateau conservative tracer sample bottles for analysis.

F.4 Conditions

1. Gas Samples
 - a. Shipped Ground in a cooler to maintain room temperature.
2. Conservative Tracer Samples
 - a. Cl⁻ samples can be shipped at ambient temperature.

F.5 Grouping/Splitting Samples

1. Conservative Tracer Samples
 - a. Organized by station in plastic, resealable bags.
 - b. Ensure each injectate sample is in a separate resealable bag.

F.6 Return of Materials or Containers

1. Gas Samples
 - a. The external gas analysis lab will return the cooler with new evacuated vials.

F.7 Shipping Manifest

Whenever samples are shipped, they must be accompanied by a hard-copy Shipping Manifest enclosed within the shipping container. In addition, a corresponding electronic version of the Shipping Manifest (csv file) must be emailed to the taxonomic ID facility and NEON’s CLA contact using the Stork Shipment Verification Tool as soon as possible after the samples have been shipped. For locations to which to ship samples, and CLA contract information, please reference CLA’s NEON intranet site, available through the sampling support library.

1. Navigate to the “Shipping Information for External Facilities” document on [CLA’s NEON intranet site](#).

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

2. Prepare a shipping manifest detailing the contents of the shipment, using the Shipment Creation and Shipment Review applications. Include a printed copy of the manifest in the shipment box (downloaded from the Stork Shipment Verification Tool).

Complete packing slip, address shipment, and ship ground to the destination(s) specified in the CLA “Shipping Information for External Facilities” document.

3. Email a digital copy of the shipping manifest emailed to the appropriate contact at the receiving analytical laboratory as well as the NEON CLA contact on the day that samples ship by submitting the shipment in the Stork Shipment Verification Tool.

F.8 Laboratory Contact Information and Shipping/Receipt Days

See CLA’s NEON intranet site, available through the sampling support library.

| | | |
|--|--------------------|------------------|

| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

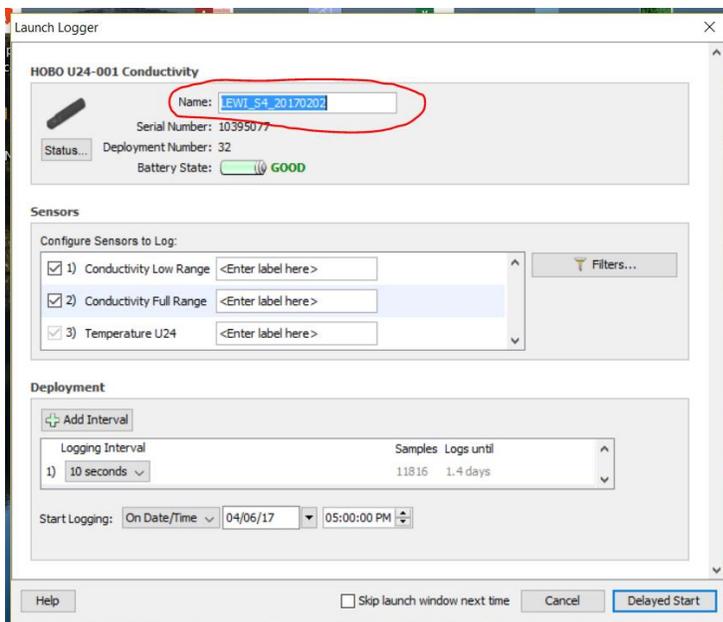

F.9 Additional Directions/Notes

1) Steps for launching Hobos

- a) Ensure HOBOWare Pro software is installed on your laptop and launch the program
- b) Connect shuttle to laptop using USB-micro USB cable
- c) Attach HOBOWare to shuttle and press power bar so that the green light shows
- d) Green light must be on for shuttle to be connected to HOBOWare, shuttle will turn off after disconnecting a device.
 - i) NOTE: If you hit launch on your computer screen when the shuttle is off your screen may still show “launch successful” even though the HOBOWare is not connected since the shuttle is off.
- e) Ensure Name is in the correct format
 - i) In the top box “Name” in the Launch window and “Description” in the Plot Setup window, follow the below format:

SITE_S#_YYYYMMDD, where S# is either S1 or S4 for reaeration station 1 or station 4

ex) LEWI_S1_20170816 OR LEWI_S4_20170816

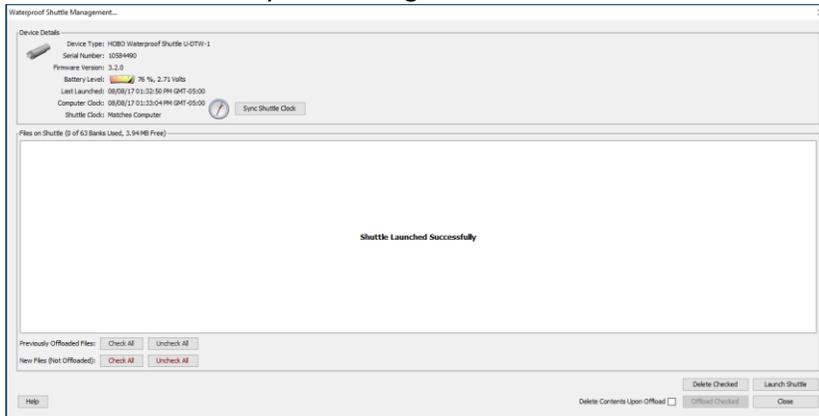

- f) Before disconnecting HOBOWare check that shuttle was powered on while launching and you can

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

check the HOBO status in HOBOWare Pro before disconnecting and this will show you if it is logging or waiting for a delayed start.

- g) Shuttle will shut off after removing the first HOBO so make sure you turn the shuttle back on when launching your second HOBO.
- i) If you do not turn on the shuttle again after launching the HOBO for S1, the HOBO for S2 will not launch successfully even though HOBOWare will indicate it was launched successfully.

- h) In summary, check to see if shuttle is on for both HOBO launches and then check the actual status of the device in HOBOWare before disconnecting the device.

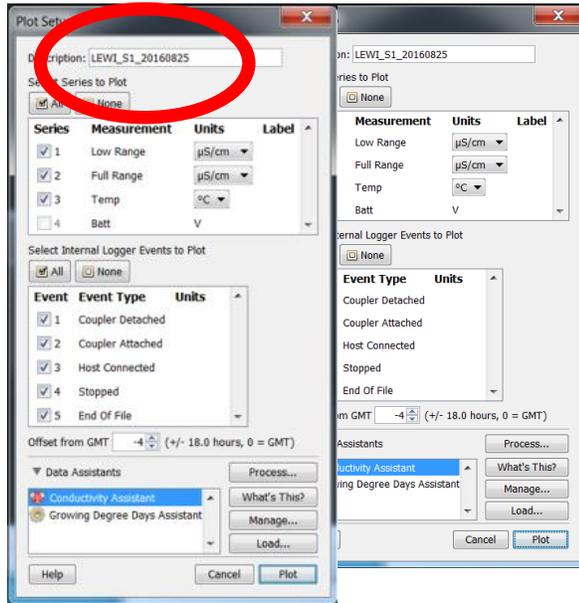

2) Save HOBO files

- a) Ensure you are using HoboWare Pro version of the software. You need the Pro version to save as specific conductance.
- b) Ensure the file Description is in the correct format:
 - i) Open the Plot Setup Window. In the top box “Name” in the Launch window and “Description” in the Plot Setup window, follow the below format:

SITE_S#_YYYYMMDD, where S# is either S1 or S4 for reaeration station 1 or station 4

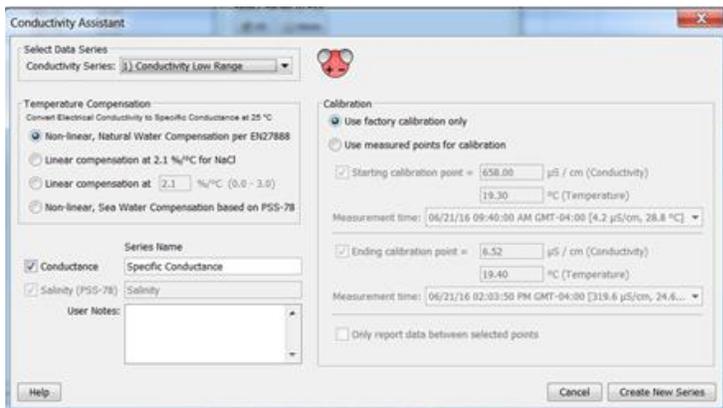

ex) LEWI_S1_20170816 OR LEWI_S4_20170816

| | | |
|--|--------------------|------------------|
| Title: AOS Protocol and Procedure: Reaeration in Streams | | Date: 02/28/2019 |
| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

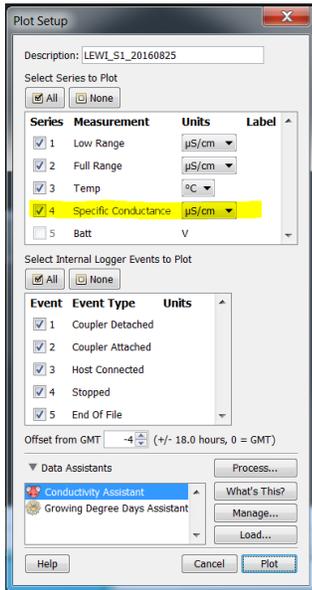

Once the description is set, it will automatically save this description as the file name when you export as a .csv file.

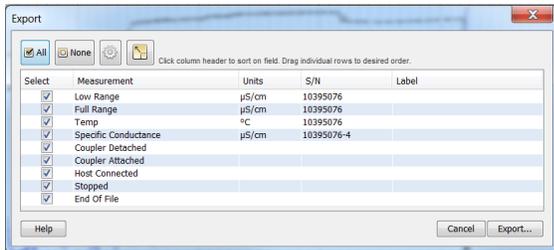

- c) Ensure temperature units are in Celsius.
- d) Ensure you select “Low Range” if Conductivity is <1000 us/cm
 - i) After reading out the HOBO, you will see the Plot Setup window below. In the Data Assistants section at the bottom, double click on Conductivity Assistant.
 - ii) In the Conductivity Assistant window, select **Conductivity Low Range** from the dropdown if your conductivity values are ≤ 1000 us/cm. Select Full range if conductivity values are > 1000 us/cm. Leave all other default settings and click Create New Series.

- e) Now you should have a Specific Conductance series listed in your Plot Window. Click Plot to view your data.

- f) Export your data by clicking on the export button  in the toolbar. Leave all of the series selected and click Export. Then save your file as a .csv with the same name as the description (the “Name” you entered when launching the HOBO).
 - i) If these names are not the same and are not in the correct format, the spreadsheet uploader will reject the file.
 - g) Upload your .csv file to the NEON spreadsheet uploader. See “How to upload HOBO files to the SOM.pdf” on the SSL – Reaeration, supporting documents.

- h) Save your hobo file to the AOS dropbox.
- 3) Troubleshooting HOBO files:
- a) If you can't find your data on the HOBO after sampling, it may have downloaded to the shuttle. Connect the shuttle and readout the device.
 - b) If you are having trouble communicating with the loggers/shuttle you may need to update HOBOWare Pro.

| | | |

| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

APPENDIX B QUICK REFERENCES: OUTLINE OF MAJOR STEPS ON ALL REAERATION DAYS

Step 1 – Measure background conductivity and collect a background Cl^- sample at each of the four reaeration stations.

Step 2 – Continuous injection of inert gas (e.g., SF_6) and conservative tracer (e.g., NaCl) – At the same time and location, add inert gas (to account for diffusion) and conservative tracer (to account for groundwater inputs) to the stream. Rate of addition depends on stream flow.

1. SF_6 Addition:
 - a. Streams with flows of $<200 \text{ L/s}$ ($0.05 - 0.2 \text{ m}^3/\text{s}$), receive approximately 100 mL/min.
 - b. Most streams $<1000 \text{ L/s}$ ($<1 \text{ m}^3/\text{s}$) can also receive 100 mL/min.
 - 1) Increase gas flow rate for very large ($>1000 \text{ L/s}$) and turbulent streams, as necessary
2. Salt Addition:
 - a. 5-15 mg Cl^-/L NaCl above background ($\sim 10\text{-}30 \mu\text{S}/\text{cm}$)

Step 3 – Collect Plateau Samples – While injection continues, take samples starting at the most upstream station (Station 1) after the furthest downstream station (Station 4) reaches plateau of conservative tracer (e.g., NaCl).

1. Collect five 40 mL water samples at each of the 4 sampling stations into pre-labeled syringes – each syringe will provide a gas and water sample. Sample from upstream to downstream.
2. Record stream temperature, conductivity and time when samples are taken at each of the 4 sampling stations. Scan barcodes and enter sample information into Fulcrum before moving to the next station.

Step 4 – Process samples (pull in air and shake for 5 minutes) at a base camp away from stream and upwind of the injection site to limit potential gas contamination. From each syringe collect a gas and water sample.

Step 5 – Store samples appropriately.

1. Gas samples → Sealed in Gas Vials.
2. Water tracer samples → Tightly sealed in labeled 60-mL HDPE bottle.

Step 6 – Measure wetted widths at 30 evenly spaced locations along the stream reach (between Station 1 and Station 4).

APPENDIX C REMINDERS

Before heading into the field: Make sure you...

- Collect and prepare all equipment.
- Pre-print labels on waterproof paper.
- Ensure all syringes are labeled with sample ID.
- Assemble and test pump.

Sample collection: Be sure to...

- Once the conservative tracer plateau is reached at Station 4, start sampling from the most UPSTREAM (Station 1) station to the most DOWNSTREAM (Station 4) station.
- Do not walk in the channel when moving between stations.
- Rinse the sample syringe twice with stream water.
- Remove large air bubbles from gas sample syringes.
- Use stopcock to ensure no sample is lost during storage or shaking.
- Shake for the full **5 minutes**.
- Over-pressurize the gas sample vials.
- Collect 5 samples at each station.
- Store in water filled, water tight containers to limit gas leakage.
- Collect 30 wetted width measurements between Station 1 and Station 4.
- Carefully record all metadata, measurements, and observations on tablet or data sheet.

Sample preservation: Be sure to...

- Keep the gas sample vials cool to limit gas expansion.

APPENDIX D CONSIDERATIONS FOR IMPLEMENTATION

- Exposing gas vials to heat should be avoided as increases in temperature can influence gas vial storage and increase the risk of gas lost. Changes in pressure (e.g., elevation changes) can increase the risk of gas lost and samples should be shipped ground. Make sure to keep vials in water when traveling to and from the site to reduce impact of elevation changes on vial pressure.
- It is extremely important that good travel time estimates be calculated. Ensure you are adding enough salt to detect and the HOBO loggers are programmed and launched correctly.
- Ensure conservative tracer reservoir does not run dry. Adjust pump rate to ensure reservoir is not depleted prior to reaching plateau and sampling. Pump rate should also be measured at the start and just before stopping the injection.
- Extremely saturated salt solution can clog the filter in the filter housing and influence the pump rate.
- Try to keep salt solutions to <50% NaCl.
- Samples must be processed away from stream to avoid contamination. Common errors include:
 - Sampling from downstream (Station 4) to upstream (Station 1), rather than the appropriate upstream to downstream sampling. Imagine that you are sampling from upstream to downstream so that you can sample the same parcel of water as it moves in the downstream direction.
 - Not sampling in thalweg.
 - Not sampling at the exact sample location in the stream (i.e. someone sampling 2 m upstream from where you are sampling for the same station)
 - Forgetting to shake syringes prior to gas sampling.

APPENDIX E ASSEMBLE AND TEST PUMP BEFORE GOING OUT

1. If piston has been withdrawn more than 2 inches from the cylinder (Figure 2a), or removed completely from the pump head (Figure 19b), you **MUST** take special precautions before reassembling pump or **Lip Seals will be damaged**.
 - a. Remove Gland Nut and install Lip Seals one at a time (Figure 2b), and ensure you do not damage the seal or the ‘lips’ (See Section 18 Piston Seal Replacement in FMI pump manual for more detail). Note, top Lip Seal should have ‘lip’ facing up while bottom Lip Seal should have ‘lip’ facing down.
2. Add a small drop of grease (high grade machine oil) to the drive pin head (Figure 19a) just before it is inserted into the radial bearing.
3. Insert piston drive pin into the radial bearing in the spindle assembly (Figure 19c). You can pull the piston out ~1 inch to make the insertion easier. Do not pull the pin out more than 2 inches.
4. At the same time as you insert the drive pin into the bearing, slide the drive carrier into the pump base assembly (Figure 19b), which will slide the ceramic piston completely into the cylinder. **IMPORTANT:** As you slide the drive carrier into the assembly, you must ensure that the knob on the underside of the drive carrier slides into the plastic slide (Figure 19a) at the same time.
5. Using the adjustment knob and the calibration scale, adjust rate to achieve the desired flow rate. If the carrier does not move when adjustment knob is turned, the knob is not properly attached to the plastic slide.
 - a. The angle of the cylinder with respect to zero (center) on the calibration scale controls the magnitude and direction of flow. Ex) If cylinder is pointed to left at 10 on the scale, the fluid will be passed from the right port to the left port at 100% of the maximum rated volume. If the cylinder is pointed to the 5 on the right calibration scale, the fluid will be passed from the left to the right port at 50% of the maximum flow rate.
 - b. Minimum Pump rates are 10% of the maximum rated flow rate.
 - c. **NOTE:** The majority of NEON maximum pump flow rates will be 1296 ml/min (Q2 piston code). Minimum pump rate for this pump is 129.6 ml/min. A Q1 piston code maximum pump rate is 576 ml/min.
6. Tighten thumbscrew (Figure 19a) to hold drive carrier in place.
7. If you need to adjust flow rate, loosen the two thumbscrews slightly and use the adjustment knob as necessary. You can change the flow rate while the pump is still pumping. Remember that the pump flow rates are very sensitive, thus small adjustments may be all that is required. Retighten thumbscrews when adjustment is complete.

APPENDIX F ESTIMATED DATES FOR ONSET AND CESSATION OF SAMPLING

See the Site-Specific Sampling Strategy Document on [AQU’s NEON intranet site](#).

Reaeration should be scheduled to capture a range of flows, so that reaeration rating curves can be created, similar to discharge rating curves. As reaeration rating curves are developed, more targeted sampling should occur to capture flows with less information and to fill in the rating curve, as appropriate.

APPENDIX G SITE-SPECIFIC INFORMATION

See the Site-Specific Sampling Strategy Document on [AQU's NEON intranet site](#).

I. [NaBr plus Salt SLUG Method](#)

[For Sites with specific conductivity values >500 uS/cm or at sites where using NaCl as a continuous tracer is not feasible:](#)

For stream sites with high conductivity water (>500 us/cm), using NaCl as a constant rate tracer can prove difficult because you cannot dissolve enough salt to see the increase and/or there are concerns about adding too much salt to a stream. In such cases, Sodium Bromide (NaBr) may be used as the conservative tracer (MX110110 for 500 g of NaBr or MX110105 for 100 g of NaBr). Salt slugs will need to be conducted at the same time, so that you can determine when to sample by monitoring conductivity with the hand-held conductivity meter at station 4.

Follow the above protocol for the continuous injection, but instead of using NaCl as your continuous tracer, you will use NaBr and a salt slug. Instructions for that are below.

- 1) Place the HOBO loggers in the stream at station 1 and station 4. Hobos should be at the same transect as the sensor sets and suspended in water. You can suspend off the sensor infrastructure. See protocol for details.
- 2) Mix NaBr constant rate solution:
 - a) Weigh out NaBr to accommodate 0.025-0.5 milligrams Bromide/L of stream discharge (0.032-0.64 milligrams NaBr/L).
 - i) For a stream with a discharge of 50 L/s, you would mix 11.6 - 232 milligrams of NaBr into your continuous injection solution, depending on site-specific needs.
 - ii) See the 'Bromide Injection Prep Sheet' tab on the Reaeration Datasheet to help calculate the amount of NaBr added to your stream.
 - iii) Note: NaBr may need to be added in higher amounts depending on stream chemistry. Thus, site specific needs will need to be worked out between FOPS, the external facility, and NEON HQ. We suggest you add on the higher range initially to ensure it can be detected at the external facility
 - b) Wear gloves while mixing the solution and be careful not to get any NaBr on your clothes so as not to contaminate samples during collection and processing.
 - c) Rinse bromide container, such as plastic bags or containers used for weighing portions in the lab, with tracer solution water in the bucket to ensure all Bromide has been added to the bucket
- 3) **Record the mass of NaBr (to the nearest 0.001 mg) and the volume of water (to the nearest 0.5 L) used for the constant rate tracer.**

| | | |
|---|---------------------------|-------------------------|
| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

- 4) Make salt slug solution of 2 kg NaCl/m³/s or 2 g of NaCl/L/s. This should be enough to see on the conductivity meter, but the actual increase is very site and condition specific.
 - a) Ex, in a stream with a flow of 50 L/s, you would add 100 g of salt. Be sure to use **non-iodized** salt. You may need to add more salt in high conductivity streams (>500 microS/cm).
- 5) **Record the mass of NaCl added** (to the nearest 0.5 gram)
- 6) Completely dissolve the salt in water (1-2 L).
- 7) **Record the volume of water used for the slug (to the nearest 0.5 L)**
- 8) At the same time as the NaBr injection is started, add the salt slug in one quick pulse into the stream at the drip station.
 - a) Do NOT pour out of a narrow mouth bottle (i.e. 4L jug), as those pour too slowly. If your concentrated solution is in 4L jug, transfer to a bucket first to add the slug in one quick pulse.
 - b) Rinse bucket with stream water and pour rinse water into stream **immediately** to ensure all salt added to the bucket made it into the stream.
- 9) Once the peak has passed and conductivity has returned to near background levels at station 4, you may begin your sampling at reaeration station 1. If you have trouble detecting the pulse at the most downstream station, follow the pulse as it goes downstream at each station to ensure it arrives at the downstream end before sampling.
- 10) Pull the loggers as the very last thing you do before leaving for the day. We want to capture as much of the declining conductivity limb as possible.

| NEON Doc. #: NEON.DOC.000693 | Author: K. Goodman | Revision: K |

II. SLUG ONLY - MODEL

For sites where reaeration will be modeled (MCDI, ARIK, and BLUE), no continuous injections will be completed, but several physical parameters will still need to be measured. This will be completed 5X/year.

Note: For sites with extremely low flows during a scheduled reaeration experiment, a limited number of these types of injections can be performed with HQ approval. However, higher flows should be targeted for future experiments and no more than 2 experiments should be performed at low flows in a given year for a single site. The constant rate tracer solution **cannot** be used in lieu of a slug solution.

- 1) Measure Discharge

- 2) Complete a salt slug: Salt slugs will need to be completed to determine travel time. Place the HOBO loggers in the stream at reaeration station 1 (sensor set 1) and reaeration station 4 (Sensor Set 2). Hobos should be at the same transect as the Sensor sets and suspended in water. You can suspend off the sensor infrastructure. Loggers should be set to log every 10 s and should be set to the appropriate units (see SOP 7F.9).
 - a. Make salt slug solution of 2 kg NaCl/m³/s or 2 g of NaCl/L/s.
 - i. Ex, in a stream with a flow of 50 L/s, you would add 100 g of salt. Be sure to use **non-iodized** salt. You may need to add more salt in high conductivity streams (>500 microS/cm).
 - b. **Record the mass of NaCl added** (to the nearest 0.5 gram)
 - c. Completely dissolve the salt in water (1-2 L).
 - d. **Record the volume of water used for the slug (to the nearest 0.5 L)**
 - e. Add the salt slug in one quick pulse into the stream at the drip station.
 - i. Do NOT pour out of a narrow mouth bottle (i.e. 4L jug), as those pour too slowly. If your concentrated solution is in 4L jug, transfer to a bucket first to add the slug in one quick pulse.
 - ii. Rinse bucket with stream water and pour rinse water into stream immediately to ensure all salt added to the bucket made it into the stream.
 - f. Pull the loggers as the very last thing you do before leaving for the day or leave them in overnight, if necessary, since it is important to collect data for the full declining conductivity limb (i.e. conductivity returns to background levels).

| | | |

| <i>Title:</i> AOS Protocol and Procedure: Reaeration in Streams | | <i>Date:</i> 02/28/2019 |
| <i>NEON Doc. #:</i> NEON.DOC.000693 | <i>Author:</i> K. Goodman | <i>Revision:</i> K |

- 3) Collect wetted widths: 30 stream wetted width measurements approximately evenly spaced throughout the reach, between Station 1 (Sensor Set 1) and Station 4 (Sensor set 2) (e.g., 10 wetted width measurements between station 1 and 2, 10 measurements between station 2 and 3 and 10 measurements between station 3 and 4). Measure the full wetted width of the stream, including under cut banks.
- a. When measuring wetted widths, the meter tape should be parallel to the ground, perpendicular to the banks, and as close to the stream as possible to get accurate wetted width measurements.
 - b. If available, a laser rangefinder can be used to measure wetted widths provided stream is greater than 2 m wide, on average. This can be done during the salt slug, as long as you are not getting in the stream. Note, that the laser range finder is not as accurate as a meter tape, thus the meter tape is the preferred measuring tool.
